THE SOVIET HIGH COMMAND: A Military-Political History, 1918-41. By *John Erickson*. (New York: St. Martin's Press. 1962. 889 pp. $15.)

When he submitted his manuscript for publication, the author of this book could not know that approaching events would give it a unique timeliness. One of his principal themes is the basic and continuing conflict between the Soviet armed services and the power complex centering on the state security service. This struggle first developed in the days of Trotskiy. It reached dramatic intensity when Marshal Tukhachevskiy fell. Since the second World War the rise and fall of military personalities has revealed discontent in the armed services. Now the treason of Lieutenant Colonel Oleg Penkovskiy has thrown an embarrassing light on the struggle between these forces. Erickson's book permits intelligence officers to study the background and development of this conflict.

The author, who did his research while a Fellow of St Anthony's College, Oxford discusses the history of the Soviet army between the outbreak of the Revolution and the German invasion of 1941. This is not a history of Soviet military institutions, but rather a discussion of the impact on the Soviet armed forces of internal politics, international developments, and leading Soviet personalities. Two lengthy chapters are devoted to the military purges of 1937, their immediate causes, and their complex effects on Soviet and world affairs. Indeed, the theme of the purges, their origins, and their effect on Soviet military policy are a major element of the book. Although he cannot fully explain the military holocaust (no one can in the present state of our knowledge), Erickson performs a useful service in summarizing the events of 1937-1938, stripping away some of the more improbable interpretations of events, and placing the purge in the perspective of its time. This perspective helps us to understand the developments of the Penkovskiy affair.

1.3(a)(4)

1. On Wednesday, 21 December, a Dr. A.D. *MERRIMAN contacted the London Embassy by telephone and somewhat guardedly reported the basic elements of what appeared to be a provocation attempt during a recent business trip he had made to Moscow. The message was reported to the KUBARK Station by the Embassy, and it was agreed that London Station would check into the report.

2. [redacted] was asked if they had any information concerning Subject. After checking, they advised that they could confirm that an individual by this name had made a trip to Moscow in early December but knew nothing about him. [redacted] also advised that he had checked with the Foreign Office who also knew nothing about the individual; but in view of the fact that MERRIMAN had stated in his telephone call to the American Embassy that he had already reported the incident to the British Ambassador in Moscow at the time, the Foreign Office was most interested since they had not received any such report from Moscow as yet. [redacted] stated, however, that the Foreign Office apparently expected that the Embassy would advise them if they planned to contact MERRIMAN directly. The Foreign Office was contacted and so advised.

1.3(a)(4)

3. [redacted] then telephoned MERRIMAN and arranged to see him at 1500 hours at his home, 59 Streatham Close, London S.W. 16. His telephone number is STR-0411.

POB USA(?)
DOB ca 1896 c.f.: US

4. (Colonel (Ret.) Dr.) A.D. MERRIMAN is approximately 65 years of age. He is a metallurgist (graduate of Cambridge) and formerly taught this subject in a technical university. He is also the author of an imposing-looking technical tome entitled: "A Dictionary of Metallurgy." During the war, he was chief Scientific Advisor attached to the Eighth Army. After the war, he went into private business, and now he is a "Technical Advisor" to the Steel Industry.

Attempted Intel Provocation

5. [redacted] called upon him at his apartment. He appeared to be completely stable and sincere, and [redacted] has no doubt that he was telling the story essentially as it happened although he was, at times, vague concerning dates and times. As he will probably be returning to Moscow again in the course of his profession, he was most anxious that his identity be protected and that no action be taken which might be traceable to him.

1.3(a)(4)

6. He lived in Moscow for about a year after the war and has since returned on business trips "several times." This last trip was at the invitation of the Soviet "State Scientific and Technical Commission." He arrived in Moscow circa 8 December and stated that he made the usual rounds of industry and talked to various people but nothing was new. On Thursday, 15 December, (maybe Wednesday) he was the principal speaker at a Scientific and Technical Commission meeting and dinner. His talk concerned the "Thermodynamic Process" in steelmaking, and he was rather surprised at the questions raised after the talk because it was quite apparent that few, if any, of the experts there really understood what he was talking about.

CS COPY

the efforts of foreign countries, particularly the United States, to obtain Russian state secrets. There are long and numerous case histories, usually involving CIA, and much emphasis on the U-2 and Penkovskiy cases. The author concludes that "Subversive actions against the socialist countries and various types of encroachments on the external security of the USSR have now been raised by the United States of America to the rank of a state policy."

There is a particularly interesting implication for intelligence in the author's consideration of the theory of territorial inviolability, which he stresses time and again as one of the most important conditions for the independent sovereign existence of the USSR. He defines this inviolability as forbidding encroachment on the territory of the Soviet Union, including its land, its territorial waters, its air space, and ships under its flag. His apparently deliberate omission of outer space from this definition, in view of other Russian positions on the law of outer space, could have very important connotations for the legality of advanced reconnaissance.

The book is difficult and turgid, but it is important to students of the Russian legal system and Russian social concepts.

INTELLIGENCE IN RECENT PUBLIC LITERATURE

ŠTA JE CIA? (WHAT IS CIA?) By *Milovoje J. Levkov.* (Belgrade; Sedma Sila. Dokumenti Današnjice, Issue No. 178. 1967. 78 pp. 2 n. din).

The author of this pamphlet received his law degree from the University of Belgrade in 1956 and his doctorate in 1965, choosing as his thesis topic international law as it pertains to espionage, with special attention to the espionage practices of various countries following World War II. The publishers mention that Mr. Levkov has previously contributed several articles to the same journal on espionage and international law.

The present article contains no startling revelations about CIA. The author's sources are basically overt, ranging from Allen Dulles' "The Craft of Intelligence," (the dust jacket of which the author or publisher has reproduced on the cover of this book) to numerous quotations from "The Invisible Government." The author also refers to other foreign authors such as Soviet Brigadier General V. A. Viktorov, who wrote "Espionage Under the Mask of Tourism" in 1963; G. Zhukov's "Plan of Cosmic Espionage and International Law" in 1960, and F. N. Chistyakov's "The Secret Front War" in 1965, to name but a few. Levkov claims that some of his information comes from "other sources" not further identified.

What Levkov writes is in fact much less interesting than the question of why he (or we should say the Yugoslav government) wanted to publish at all, unless mainly for internal consumption in connection with the revelations made at the time concerning the plans and activities of Alexander Rankovich. The author's major object, it appears, is to attempt to prove that espionage is contrary to all forms of international law. The reader is supposed to infer from his slanted statements that *only* CIA is engaged in international espionage.

Levkov delves into the history of CIA and mentions its early beginnings, including the role of the OSS, which he says was engaged in a variety of special intelligence missions and supported underground anti-Nazi groups deep in occupied territory. In addition, the author comments on the role of OSS in the invasions of Normandy and North Africa. For reasons best known to himself, the

[redacted]
Approved for Release
22 JUN 1990

author chose to ignore the fact that OSS was in the mountains of Yugoslavia helping Marshal Tito in his struggle against the Axis powers.

Levkov refers to most of the other US intelligence agencies, all of which we are to understand are under the control of CIA. He believes that CIA has some 20,000 staff employees and approximately 200,000 agents throughout the world. As far as he is concerned, the US government cannot do anything in the realm of global strategy and politics without the approval of CIA. He pictures CIA as an organization beyond any real control. He apparently wishes to amuse his readers by giving a literal translation of the Watchdog Committee, i.e., that they are "dog watchers," implying that CIA is an organization of dogs that must be watched carefully. He attempts to explain the role of the National Security Agency (CIA-controlled) mostly from excerpts of the 1960 press conference given in Moscow by defectors Martin and Mitchell. In presenting the readers with an idea of how CIA operates (against international law), he makes references to the Berlin tunnel of 1956, CIA's activities in Iran (1952), Guatemala (1954), Indonesia (1958), Cambodia (1960), Laos, Vietnam, the U-2 affair, the use of Samos and Midas as spy satellites, the Bay of Pigs episode, British Gulana (1963), the National Students Association, penetration of Western European labor unions, purchases of news media, political assassinations, psychological warfare in Vietnam, Camelot, Svetlana Alliluyeva, and Colonel Oleg Penkovskiy.

Despite the western literature presumably available in Yugoslavia, the author chooses to side with the Soviets in the Penkovskiy case. He makes no reference to Penkovskiy's having been a GRU officer and points out that Penkovskiy was a mere reserve officer in the Red Army. He debunks the information given by Penkovskiy and implies that he became an agent for money and no other reason. It is interesting to note that the author, who, we have been told, is an expert at international law, defends the right of the Soviets to arrest Greville Wynne in Budapest "due to a legal agreement between the USSR and Hungary." Then we learn that Wynne was "traded for Gordon Lonsdale (alias Konon Molody), a Soviet citizen arrested in Great Britain for espionage.

Levkov depicts the defection of Stalin's daughter as a CIA operation timed to embarrass the USSR during the celebration of the 50th anniversary of the Revolution. According to Levkov, Svetlana Al-

[redacted]

Iliuyeva is "two million dollars richer thanks to the actions of CIA." Levkov claims that CIA prepared her book of 80,000 words from CIA archives in Frankfurt. Levkov refuses to believe that she wrote her book three years prior to her defection, apparently because he does not believe her story that she found little difficulty getting her manuscript out of the Soviet Union.

Levkov seeks to leave the reader with the impression that the US government revolves around the CIA. He presents a chart showing all US intelligence agencies (CIA, NSA, FBI, and the Department of State's INR) as being under the control of CIA. When the author comments on psychological warfare, the reader is to understand that the numerous organizations overseas he refers to are really CIA organizations, including the Voice of America.

The author appears to be very frustrated because international law does not seem to be able to cope or curtail espionage, i.e., CIA activities. In his final paragraph he warns nations to look after their individual security and to defend themselves from the "dangerous acts of CIA." In order to strengthen his point, the publishers have a cartoon (drawn by D. Savich but of the type usually found in Soviet periodicals) on the back cover showing a man with CIA written on his chest and sitting on the globe so that he can cover the entire world. In addition to the usual capitalistic cigar in his mouth, the CIA operator has six hands. They hold a telephone, microphone, hand grenade, pistol, and dollar bills.

Unfortunately, Mr. Levkov does not give us any references to his doctoral work in which he allegedly wrote about more than one country. In this article he appears to accept the fact that no country has admitted to being engaged in international espionage and he, therefore, comes to the conclusion that the US is the only country involved because CIA admitted to such activity in 1960 during the U-2 affair.

[redacted] 1.3(a)(4)

ATTACHMENT

SUBJECT: Declassification of Special Collection of Soviet Military Thought

1. We consider the publication of The Penkovskiy Papers has done a rather creditable job of inviting world-wide attention to Soviet subversions and KGB activities and that we have, for a change, the initiative in a major segment of the propaganda field. The climate is favorable for trying to maintain the momentum that The Penkovskiy Papers has achieved. The next step should be one related to the book. We feel this is logical because the name, Penkovskiy, is now a familiar one, it is news and therefore can get into print without undue effort, and any subsequent and related efforts will help keep the book an active and saleable item.

2. A reasonable way of utilizing these factors would be to declassify the Special Collection of Soviet Military Thought and related items obtained from Penkovskiy on Soviet strategic thinking. As you know this comprises about 5,000 pages, which have been published in 130 clandestine service reports of which 89 have been released to NATO services. Placing this material in the public domain would serve, we believe, a variety of purposes, none of them immediate and spectacular but all of them significant for the long term.

A. Firstly, the mass of the material, its subject matter and the level of its classification totally dispel the charge that Penkovskiy was a minor agent of limited access. For the same reasons, the charge that The Papers were fabricated in the West would be mitigated, we believe. To have the whole collection available for open research would incline skeptics to grant that certainly Penkovskiy's channels to the West permitted a high rate of flow for information and, furthermore, that the source materials supplied by Penkovskiy were substantial and, consequently, adequate to fill a book like The Papers without resort to other sources or to the author's imagination. Note that this argument deals only with the question of the authenticity of the work, not with the identity of the editor. We grant that making these articles available to the public would not strengthen the CIA disclaimer of sponsorship for The Papers. We doubt, however, that the rift in that would be at all

APPROVED FOR RELEASE
[redacted] 1.3(a)(4)

impaired. Declassification would, some half a year after the storm of controversy in the press, be a welcome if quiet fanfare and it would only emphasize a point already alleged in the book, (I have sent the entire Special Collection to my intelligence contacts. (P. 267, Doubleday Edition) Naturally, no official attribution to any source or overall praise would be made at the time of declassification. As noted in paragraph one, above, we would expect the collection to be ignored in the press with Penkovskiy of course, but would expect that the controversy of the fall would not revive. Stale news rarely attracts editors.

b. Secondly, the corpus as a whole should have a growing influence on the understanding of Soviet military plans among scholars, journalists, disarmament negotiators and so on. The simple lack of anything more repugnant than the Sokolovskiy book from the Soviet side in comparison with the enormous Western literature on the subject has influenced many people to assume that only Western planners deal in such concepts as pre-emptive war.

c. Thirdly, among the mass of material there are some particular articles that can be especially exploited; these would be best introduced into the public domain accompanied by the full collection.

d. Fourthly, we believe that the product of scholarly research into this material would probably be of intelligence value in other fields, some of them remote from military strategy, such as sociology and internal Soviet politics.

3. As an explanation for declassification of the materials, it could be said by an official of the Agency overtly releasing the materials that not privately, the documents in question are known to the Soviets and are in Western hands by duplication from Penkovskiy's [redacted] from the specific statements in the Penkovskiy Papers.

4. If your service is amenable to the proposal, we would proceed along the following lines:

a. Prepare a complete set of the collection in English and in Russian in a format devoid of [redacted] service references, numbers, etc. The Russian copy would be

1.3(a)(4)

[redacted]

Page Three

photographic copy of [redacted]

[redacted] Normally the [redacted] intention according to ordinary procedures and [redacted]

[redacted] Assuming that the [redacted] concurs announce the availability of the material according to their customary procedures. We anticipate that this will contain an [redacted] respectability of the document and will [redacted] the basis for [redacted]

[redacted] In making this proposal we have considered many factors, including the [redacted] that such a move will help the [redacted] and that several liaison services will become aware that we did not pass all the reports [redacted]. We do not consider those problems as persuasive enough to abandon the proposal. We still have on hand sufficient numbers of copies of the reports of this type that were not passed to liaison services to complete the distribution [redacted] if deemed necessary. We doubt that there would be much interest in them for liaison, however, and are therefore reluctant to undertake the job, but we have no objection in principle to doing so.

6. The concurrence of your service in the proposal outlined in paragraph four above is requested as soon as possible. Should your service prefer to [redacted] material and surface it, we should be happy to support you in any way we can.

7. An early reply will be appreciated.

OTVETSTVENNOST' ZA IZMENU RODINE I SHPIONAZH (Liability for Treason and Espionage). By *Grigoriy Zakharovich Anashkin.* (Moscow, 1964. 198 pp.)

This treatise on the Soviet law of treason and espionage is by the Chairman of the Collegium for Criminal Cases, USSR Supreme Court, so there can be little doubt that its views are authoritative. The book appears to be one of the numerous efforts to demonstrate the legitimacy of the Soviet legal system and its protection of the rights of individuals. It recounts the injustices of the Stalin era made possible by the looseness of the criminal laws and the failure to develop a specific philosophy of the crimes of treason and espionage. It then attempts to demonstrate that these weaknesses have been overcome and that the contemporary law of treason and espionage is precise and requires proof of the violations alleged.

To the Western mind the case is not fully made, although there is no doubt some progress and definition have been achieved. At one point, for instance, the author indicates that it is not the nature of the information that makes seeking it an act of espionage but the fact that it is collected on behalf of foreign intelligence in accordance with an assignment. This concept and the territorial sensitivity it reflects account for such bizarre things as the charges against Professor Barghoorn and the more recent tragedy of Newcomb Mott.

The main intelligence interest of this volume is its extensive justification for stringent espionage and treason laws, a justification based on

7. A rather friendly Russian type named fnu PENKOVSKY took him in hand after the meeting and returned with him to his hotel (the Leningradskaya) along with another Britisher. The three had a drink in the bar, and the British companion left for bed. PENKOVSKY asked MERRIMAN if he had any spare cigarettes, and they proceeded to his hotel room so he could get some packs that he had in his suitcase. Once in the room, the Soviet locked the doors, turned the radio up as loud as it would go and produced from his coat pocket a folded pack of paper wrapped in cellophane. He stated that they were secret documents he wanted to be put in the hands of the American Embassy but that he could not turn them over to MERRIMAN but only to an American officer personally. He asked MERRIMAN to telephone the American Embassy and ask for an officer to come to his hotel room. MERRIMAN refused to make the call or to even touch the papers; and the Soviet, after pleading with him for a little while, put the papers away and departed. He was not angry and was around again and underfoot for the remainder of his visit and did not mention the matter again. MERRIMAN at first felt that he should advise the American Embassy about the occurrence but then felt that this, his visit to the American Embassy, might be observed by the Soviets; so he told the British Ambassador about the affair on the following day.

8. He was subsequently advised by two of his British colleagues that they had noticed that he was under close surveillance. MERRIMAN stated that he himself did not bother about this or even try to spot them as he was indifferent to it--having lived in Moscow in more difficult times.

9. Nothing else happened until Sunday at the airport when he was leaving to return to the U.K. PENKOVSKY showed up at the airport about five minutes before departure time. He called MERRIMAN aside and stated that he realized that MERRIMAN was reluctant to become involved, but it was really most important that he establish contact with someone in the American Embassy and asked if MERRIMAN could advise the Americans (presumably upon his return to the U.K.) that PENKOVSKY would be waiting by his home telephone (717184) every Sunday at 10 a.m. for the call and that all the American had to do was to call that number and he would give him further instructions. MERRIMAN was non-committal but asked PENKOVSKY where his "home" was, and PENKOVSKY stated that he lived at 11 Gorki Street. MERRIMAN stated that this was, in fact, the Office of the Scientific and Technical Commission.

10. MERRIMAN stated that there was nothing outstanding about PENKOVSKY that could be used to identify him. He was about 55 years of age, of average height, average build for a Russian, and had no outstanding features. He spoke English well but with the usual heavy Russian accent. He had a pleasant and engaging personality which made it a pleasure to be with him. PENKOVSKY attended the dinner and the speech, and he had seen him around once or twice before at official functions during the trip. He stated that he was an engineer, but MERRIMAN felt that he did not have any real knowledge of engineering other than some of the terminology.

11. MERRIMAN is, understandably, anxious that no one take advantage of the telephone number and attempt to call it because this might get him involved and prevent further trips on his part. [redacted] 1.3(a)(4) assured him that KUBARK would take no action of any kind, that his confidences would be carefully protected and that his bringing this incident to our attention was deeply appreciated. Mr. MERRIMAN has [redacted] name and office telephone number and stated that he would immediately advise [redacted] if he hears anything further from this or if, on subsequent trips, he again becomes involved with anything which might affect U.S. interests.

PERTINENT INFORMATION

2. WHEEL is forwarding the enclosed packet for COMPASS' earliest perusal. CHISEL has been requested to pass on the materials for COMPASS to study in the manner in which he deems most secure and practical.

4. Re CHALK. WHEEL is enclosing the necessary briefing guides including original site diagrams, paint specimens, and map of locale. COMPASS should, of course, expedite the casing as muchas possible, but not at the expense of his security or the quality of the casing. It is proposed that COMPASS first stroll past the drop site for external observations, and later, at an interval of several days, enter the site area and place a telephone call to a pre-arranged contact (preferably CHISEL) or absenteed SQUARE acquaintance--whose absence has previously been ascertained. After a thorough casing examination of the proposed dead drop site, COMPASS should case the proposed signal site. This casing can be done simultaneously with the casing of the dead drop site. It is believed that it is unnecessary to physically enter the signal site proper. A passing, external inspection should be sufficient. With regard to the American House drop site, WHEEL tentatively proposes to have CHALK proceed down the right-hand side of Turchanin Ulitsa (toward the Moscow River) at a specified date and time (2300 hours on four consequtive Saturdays until drop is effected). COMPASS will be on the other side of the wall to effect the recovery. The afore-mentioned plan is contingent upon COMPASS' casing of the area and recommendations for implementation of the plan. If pictures can be taken of Turchanin Ulitsa and from inside the American House courtyard of the wall and area, it would be appreciated. However, COMPASS should determine the practicality of this in terms of security.

[redacted] on straight line to Sokol'niki instead of Great Circle Route. At end of line got off, visited old church to left on direct line from Sokol'niki Metro Station, then proceeded to Sokol'niki Park and strolled about. Saw Amer. Exhib. Fuller building which fenced off, then returned to Sokol'niki Metro Station for trip back to town. After studying map on subway car, decided to get off at Okhotniy Ryad and on exiting had choice of Pushkinskaya St. or Smolenskaya Ploshchad. Went out on former, stopped men's room just up street from subway and went on.

2. COMPASS hasn't a map so can't retrace his steps on paper. It shouldn't be too difficult to trace. Up Pushkinskaya--this wasn't planned as my last letter should indicate--subway errors and the choice put me on Pushkinskaya--and the stores are as indicated by our friend. Didn't spot the doorway but the meat store has an entrance on Pushkinskaya (P. from now on). It isn't used, so far as a quick glance would tell. The ladies' shoe store is there on P. Across from the meat store is a book store where COMPASS looked around for [redacted] line on the sidewalk into the meat [redacted]

Page 3 Sketch

4. COMPASS continued on [redacted] up in a square where the Gorol station is [redacted] put me on the road to the Embassy on, COMPASS thinks, Arbatskaya. Passed Sudanese and Hungarian Embassies on the route--by the way, this is all on foot!--and a check with a second Militiaman sent COMPASS straight ahead to the end of the street to take left towards the Embassy.

5. Taking left then, passing the Embassy, COMPASS entered a barber shop on a corner but it was too crowded so exited to continue on to America House. Stayed on left side of street in direction [redacted]

14. **2. Re CHALK: WHEEL notes in Letter No. 1 that COMPASS states that CHALK will "have had it at night" if he throws a package over the wall. SLEDGE requests that COMPASS detail the reasons why COMPASS feels that the wall site would be bad or unsuitable. Is there 24 hour DRILL on Turchanin Ulitsa? Is the DRILL mobile or fixed? If there is 24 hour DRILL on Turchanin Ulitsa, then, presumably, the window site would also be compromised. SLEDGE remembers the basement window site, but wonders how CHALK could pass a packet through the closed window or can they be opened so that the packet could be pushed directly into the dining room? Could, as COMPASS states, CHALK actually toss a package through the window from the sidewalk or would CHALK have to step off the sidewalk to approach the window, bend down, and insert the package through the bars and window? This window site sounds as though it might have possibilities. COMPASS should case and study in detail this site and compare and make a careful evaluation of whether the window or wall would be the better drop site for CHALK'S security and for COMPASS'. Moreover, if COMPASS holds that both neither site is suitable, he should not hesitate to state such together with detailed reasons for rejecting the proposed site. If the JIG site is rejected, it will be incumbent upon COMPASS to locate and detail an alternate site filing the measurements requested by chalk; i.e., 8 1/2" x 5 1/2" x 1/4". WHEEL would appreciate sketches and inside photographs (if possible) of the window area. COMPASS should be able to borrow CHISEL's or a friend's camera over night for use in taking some inside shots. WHEEL would also be desirous of having photos taken (from inside the courtyard) of the proposed wall area and immediate courtyard vicinity. COMPASS could use the puppy as an ostensible subject and reasons for photographing this outside area. As soon as possible, COMPASS should, after dark, attempt to walk down Turchanin Ulitsa toward the river and try to ascertain the presence of fixed or mobile DRILL--especially in place in front of him along Turchanin Ulitsa. If possible, this should be done several times, and since COMPASS resides at JIG it will be viewed as a normal route to JIG from SQUARE.**

3. To more important matters. Two observations have been made of the drop site and one more of the signal site with some gain. Tosca were afoot. One observation was made by chance in a taxi on the way to the Bolshoi, Kash in turn, as I consult my notes.

6. On Friday, Nov. 25, at 2100 hours Compass walked by the Pushkin St. site. See attached map number 1. The walky was made from the direction of the Kremlin and along Theatre Street to Gorkiy after giving the Kremlin Square and the GUM store a complete walk around. The lights in the shoe store were still on and reflected brightly on the street. There was much foot traffic. There were lights still on in the meat store but few customers. It was closing time. Hours are from - another note - 0800 to 1900 hours with lunch from 1300 to 1400. The paper goods shop was closed, so it may be that it is closed on Friday, although Monday is the usual closing day for such shops. Must check that later. As the map indicates there are repairs going on across the street and there is a crane servicing the lifting problems. As I've already mentioned, Compass believes, any spot could be permanent surveillance but there is no way to know. It is very easy to establish if they want. After going up Gorkiy from observation of the drop site, Compass noted that there was a continuous stream on foot traffic and trucks making food delivery on Kuznetsky. Regarding both directions as comprising the foot traffic.

	7. SOURCE CRYPTONYM / 8. DATE OF INFO. / 9. EVALUATION

1.3(a)(4)

1. COMPASS hopes the report requested to come [illegible] in pouch of that date was received. The cable reply to your cable request was sent on the assumption Jan. 27 report was in D.C. and that it had just not gotten to your office. It was assumed further that if anything had gone wrong with the pouch CHISEL would have been one of the first to know, and as of Feb. 1 afternoon he had heard nothing.

2. COMPASS will try to fill out the basic dead drop and signal site report on Feb. 4, and follow instructions of Letter No. 8 on Feb. 5. COMPASS told CHISEL the Letter No. 8 consisted of personal financial problems so that COMPASS had an excuse to kepp the letter in his possession--to permit him to memorize telephone message to be given to CHALK on on Feb. 5 at 1000 hours after 0900 Mass at Fr. Dion's. COMPASS still has the letter for reference, but will destroy it before he goes out on Feb. 5, 1961, to telephone. It will all be memorized by that time.

3. COMPASS will destroy Letter No. 8 himself instead of putting it in CHISEL's burn bag, after it has served its purpose. In future, please, when letter contains specific "EYES ONLY" instructions, avoid putting "SECRET EYES ONLY" stamps on the letter. They add nothing to COMPASS control of his mail.

4. COMPASS hopes the following amendments to your instructions of Letter No. 8 will be acceptable. They are based on his experience here and use of public telephones. First, even if a male answers the phone on Feb. 5, COMPASS will use familiar Russian for "Hi, Oleg!" /

_/ If the answer is "Yes!" /Da!/ COMPASS will reply, "Reply only in Russian. This is your intimate friend!" /

_/ Then COMPASS will continue in English. If CHALK tries to insist on knowing who is calling, COMPASS will insist "Listen!" in English and go on as instructed. CHALK must have some guide to a cover story in case he is not alone when COMPASS calls and, in the event the number is wrong, or a male answers who is not CHALK, the use of the familiar Russian should allay suspicion.

5. Other instructions in Letter No. 8 will be followed "to the letter" insofar as faulty memory may preclude. A cable would be sent saying "Contact established." except that CHISEL would have to send it and [illegible]

FILE THIS FORM IN FILE NO. [redacted]-Operations

7 USE PREVIOUS EDITIONS. (7-46)

APPROVED FOR RELEASE
31 MAR 1992

DOCUMENT TRANSFER AND CROSS REFERENCE

and COMPASS worries about such transmission under rules as established in Letter No. 8. Better that COMPASS should get his report out by sealed pouch on Feb. 7 which you should have by Feb. 10. That would avoid any awkward cover story to CHISEL, particularly since COMPASS will not be returning Letter No. 8 but will have destroyed it--most securely, by burn, crush, and flush method!--and CHISEL may be concerned about COMPASS' handling of letters from you.

11. re JIG: COMPASS would be happy if this report could be a definitive review of all reporting re JIG but the evening is passing swiftly. It was a rough day physically and tomorrow will also be a rough day in the same way. This GSA job is no "lark," particularly as I have more responsibility as a Bldg. Super, than as GSA. U.S. buildings in Moscow are held together by by paint and mutch is required of the GSA become Bldg. Super. (Nerve wracking, too!)

12. JIG description as forwarded as thought to be complete, particularly as missing details as requested, when not specifically answered, were assumed to have been accepted as resolved. When COMPASS stated he would be in place when, where, and as how requested, it was assumed you understood it was all thought out and COMPASS could handle the situation. Every detail can't be reported because too many things happen too fast. COMPASS has run into the latest complicationsthis past six weeks as concerns "JIG."

13. BUROBIN, in response to a year old request of the Embassy, is going--was going--to tear down storehouses in the backyard of JIG. (The Sketch on rear of this page crossed out and put on last page of this report plus plans of JIG previously forwarded should give you the idea!) To date, BUROBIN still has not come through and COMPASS personally isstuck with the problem. Essentially, they are to tear down deteriorated storehouses and install brick wall, where it does not exist, in JIG compound. Six weeks have passed and they still are not here to do the job. That, however, is a detail, for, under any type of surveillance observation COMPASS still has many excuses to be in JIG's rear yard. Visit storehouses; play with dog; clear snow off skating rink; walk for fresh air--anything, and all legitimate.

14. COMPASS would need a full three hours to give the same time he has given to this report in general, to a report on all the ramifications of JIG as a "dropsite" as planned. He doesn't have the time now if he is to handle cover job tomorrow.

15. Next report--phone call to CHAIOS. After that--or pertaining with it--detailed report on JIG.

Мой, дорогой Господин!

Прошу довести до соответствующих компетентных лиц Соединенных Штатов Америки следующее.

К Вам обращается Ваш большой друг, ставший теперь уже и Вашим солдатом-бойцом за дело П р а в д ы, за идеалы истинного свободного Мира и Демократии для Человека, которым Ваш /а, теперь и мой/ ПРЕЗИДЕНТ, ПРАВИТЕЛЬСТВО и НАРОД отдают так много сил.

На этот путь борьбы я стал сознательно. Этому способствовало многое. Последние три года явились в моей жизни очень переломными, как в образе мышления, так и в других вопросах, о чем доложу после.

Я долго и много думал. В настоящее время принял зрелое и для себя окончательное и правильное решение, которое и побудило меня обратиться к Вам.

Прошу поверить в искренность моих мыслей и желаний быть полезным Вам. Я хочу внести свой, может быть скромный, но, на мой взгляд важный вклад в наше общее Дело, и впредь, как Ваш солдат, выполнять все, что мне будет поручено.

Можете не сомневаться - этому новому долгу я буду отдавать все свои силы, знания, жизнь.

Обращаясь с вышеизложенным, хочу сказать, что работу за новое Дело я начинаю не с пустыми руками. Я отлично понимаю и полностью отдаю себе отчет в том, что к правильным словам и мыслям необходимо приложить и конкретные доказательства, подтверждающие эти слова. Определенные возможности для этого у меня были и есть.

В настоящее время я располагаю очень ценными материалами по ряду вопросов, предстовляющих исключительно большой интерес и государственную важность.

Эти материалы я хочу срочно передать Вам для их изучения, анализа и последующего использования. Сделать это необходимо как можно быстрее. Форму передачи этих материалов определите Вы сами. Желательно передачу осуществить не через личный контакт, а через тайник.

Еще раз прошу - как можно скорее "освободите" меня от подготовленных материалов; это целесообразно сделать по многим деловым соображениям.

Ваш ответ: о порядке, форме, времени и месте передачи указанных материалов прошу сообщить мне /желательно на русском языке/ через мой тайник №1 - /см.его описание и порядок использования/.

Если Вы определите мне для передачи свой тайник, то прошу учесть, чтобы размеры последнего позволяли вместить материалы, размером с книгу - "Вэн Клайберн"-С.Хентова,1959 года издания.

После того, как Вы получите от меня материалы, желательно организовать во второй половине августа с/г личную встречу с Вашим представителем. Нужно подробно поговорить о многом. Прошу для этого 4-6 часов. Для меня удобно с субботы на воскресенье. Место и порядок проведения этого мероприятия определите Вы сами.

По всем поднятым вопросам жду Ваших указаний через тайник №1 начиная с 9 /девятого/ августа 1960 г. /- с 9 /девятого/ августа/.

Прошу в работе со мною проявлять полную конспиративность, осторожность и не допускать никаких условностей. Берегите меня.

Да помогут нам в будущей совместной работе справедливые идеи и цели, которым я и посвящаю отныне себя.

Всегда Ваш .....

19.7.60.

P.S. Большой, большой привет моему первому, хорошему другу - полковнику Charles Morgan Peter и его жене. Мысленно шлю приветы моим знакомым: Colby, Koehler, Ditta, Beckett, Daniel, Glazebrook и пр.

Я с чувством большого удовлетворения вспоминаю время, проведенное с ними.

APPROVED FOR RELEASE
31 MAR 1992

Планировал до 9.8.60. встретить Вашего представителя и вручить настоящее письмо, но из этого ничего не вышло.
Приходится пока сделать перенос на 15 августа.

Translated from Russian

My dear Sir!

I request that you pass the following to the appropriate authorities of the United States of America.

It is your good friend who is turning to you, a friend who has already become your soldier-warrior for the cause of Truth, for the ideals of a truly free world and of Democracy for Mankind, to which ideals your (and now my) President, government, and people are sacrificing so much effort.

I have consciously embarked upon this path of struggle. Many things have contributed to this. In my life, the last three years have been very critical, both in my way of thinking and in other things, about which I will report later.

I have thought long and hard. Now I have taken a mature and for me, a correct final decision which has impelled me to approach you.

I ask that you believe the sincerity of my thoughts and desires to be of service to you. I wish to make my contribution, perhaps a modest one but in my view an important one, to our mutual cause, and henceforth as your soldier to carry out everything which is entrusted to me.

You need not doubt that I will give all my strength, knowledge, and my life to this new obligation.

In presenting the above, I want to say that I am not beginning my work for my new cause with empty hands. I understand perfectly well and take into full consideration that to correct words and thoughts must be added concrete proof confriming these words. I have had, and do have now, a definite capability to do this.

APPROVED FOR RELEASE
31 MAR 1992

At the present time I have at my disposal very important materials on many subjects of exceptionally great interest and importance to your government.

I wish to pass these materials to you immediately for study, analysis, and subsequent utilization. This must be done as quickly as possible. You will determine the manner of transmittal of this material yourself. It is desirable that the transfer be effected not through personal contact, but through a dead drop.

Again I request that you "relieve" me as quickly as possible of this material which I have prepared; this should be done for many valid reasons.

Your reply: Please inform me (preferably in the Russian language) through my dead drop No. 1 (see its description and manner of use) concerning the manner, form, time, and place for passing of the indicated material.

If you designate your own dead drop for my passing the material, please tkae into consideration that your drop should be able to contain material equivalent in size to the book, Ven Klaybern, by S. Khentov, published in 1959.

After you receive the material from me, it would be desirable to arrange a personal meeting with your representative during the second half of August of this year. We must discuss many things in detail. I request four to six hours for this. Saturdays and Sundays are convenient for me. You decide upon the place and manner of setting this up.

I will wait for your orders regarding the questions raised above, through Drop Number 1 starting from 15 August 1960.

I ask that in working with me you observe all the rules of tradecraft and security, and not permit any slipups. Protect me.

May the justice of the ideas and goals to which I am

devoting myself from this day forward aid us in our future collaboration.

Always your .....

19 July 1960

P. S. My best, best greetings to my first good friend, Colonel Charles MacLean Peeke and his wife. Mentally I send greetings to my friends: Cotter, Koehler, Ditta, Beckett, Daniel, Glassbrook and others. I remember with great pleasure the time I spent with them.

I had planned to meet your representative and pass him hhis letter before 9 August 1960, but it did not work out.

Now, this must be postponed to 15 August.

(3)

My dear sir!

I request that you pass the following to the appropriate authorities of the United States of America.

It is your good friend who is turning to you, a friend who has already become your soldier-warrior for the cause of Truth, for the ideals of a truly free world and of Democracy for Mankind, to which ideals your (an now my) President, government, and people are sacrificing so much effort.

I have consciously embarked upon this path of struggle. Many things have contributed to this. In my life, the last three years have been very critical, both in my way of thinking and in other things, about which I will report later.

I have thought long and hard. Now I have taken a mature and for me, a correct final decision which has impelled me to approach you.

I ask that you believe the sincerity of my thoughts and desires to be of service to you. I wish to make my contribution, perhaps a modest one but in my view an important one, to our mutual cause, and henceforth as your soldier to carry out everything which is entrusted to me.

Always your . . . . . .

19 July 1960

P. S. My best, best greetings to my first good friend, Colonel Charles MacLean Peeke and his wife. Mentally I send greetings to my friends: Cetter, Koehler, Ditta, Beckett, Daniel, Glassbrook and others. I remember with great pleasure the time I spent with them.

I had planned to meet your representative and pass him this letter before 9 August 1960, but it did not work out.

Now, this must be postponed to 15 August.

*Subject typed the letter on a Cyrillic typewriter. He wrote in the American names.

(8)

Translated from Russian

My dear President,

In my first letter of 19th July 1960, I have already told you that I have reappraised my place in life and about my decision and readiness to devote myself to the Cause of a struggle for a true, just and free world for humanity. For this Cause I will fight to the end.

I ask you to consider me as your soldier. Henceforth the ranks of your Armed Forces are increased by one man.

You can have no doubts about my devotion, steadfastness, selflessness and resolution in the battle for your Cause (which is also mine). You will always be satisfied with me, you will always remember me with a good word. Your acknowledgement - I will earn it. For this a great deal of time will not be necessary.

I have certain personal requests

(1) I request you to look into the question of granting me from this moment citizenship of the U.S.A. (or of Great Britain.) I also ask you to grant me at your discretion a military rank in the Army of the U.S.A. I have sufficient knowledge and experience and not only now but also in the future I will be able to bring you most definite benefit working in the U.S.A. itself, a prospect of which I dream a lot.

(2) I ask that you should give instructions on the careful, deliberate and conspiratorial work with me on the part of your workers.

(3) At the present moment I am handing over a series of materials which I have gathered during the last year. I ask for your directions about their assessment and about a decision on a fixed sum for this work since I have no special savings and money will be necessary in the future. I ask you to put the sum which is granted to me in an American bank.

APPROVED FOR RELEASE

31 MAR 1992

These are my personal requests.

Once again I assure you of my boundless love and respect for you, for the American people and for all those who find themselves under your Banner. I believe in your Cause. I am ready to fulfill any of your orders. I await them.

I remain,

Always yours,

14th August 1960
9th April 1961

[redacted] Letter No. 1 [redacted]

1.3(a)(4)

1 October 1960

1. COMPASS arrived in city 1 October from Helsinki and settled into Japanese House in corner room [redacted] with large ** window facing on corner. Will be here three [redacted] My interpreter returned only last night at 1800 from a trip to [redacted] unable to write. He left on an internal trip 4 or 5 October. This will be short for not being written at lunch hour at America House and [redacted] give some perspective since I'll ride back with a group [redacted] country in winter months, I'll have to destroy it for I have no safe keeping facility. The Moscow is good but [redacted]

2. Surveillance coverage so far rated is light. Have made no checks for it but even then it is obvious. October 9 made tour from America House to church with a friend to church on old [redacted] Recognized one of the military men and he said we have two cars on us. From house went to plumbing supply store behind Ukraine Hotel and spotted no coverage, but there is an easy area for discreet coverage. Went into Ukraine buy guide book and map and then walked to Embassy, Chaikovski and down Gorkiy. Crowded sidewalks and spotted only one man who entered bookstore with me. Bookstore was mobbed so went to GUM where impossible to detect coverage. Walked to Kremlin, mausoleum closed, and on into St. Basil's. One young man, 25, 26--and two older ones--35-40--on my tail and close. From St. Basils down to Naberezhnaye along river and I'm positive man at end of street at wall along river was my friend covering me for the three in St. Basils. I made no attempt at any time to look behind me.

3. Reaching the large heated swimming pool in a park on the same road along the river to America House, I strolled in, and there were two new ones, undoubtedly on me. Not my imagination, and there were no repeats spotted in any of my coverage.

4. Back to the river border and on to America House where I strolled around the side along the House to the swimming pool in back, through there checking the hours it was open and I spotted four or five possible "friends" and one positive as I strolled down the block across from the bridge and the bus stop. The positive was a girl about 25 strolling ahead of me who foolishly turned about half way down the block to gesture twice to whoever was behind me that they should hold off. She then crossed the street to go under the bridge and make sure from there that I returned to America House. Lord, how they communicate I don't know but the area is simple to cover.

[redacted]

APPROVED FOR RELEASE
31 MAR 1992

[redacted]

5. I'm sure they have coverage from the building facing down over the [redacted] but it doesn't cover the corner wall we discussed for GRUNION. I have official day-time access--can't detail now--and can have official evening access to back yard [redacted] I can't give my position as building superintendent too far in advance (don't want to jeopardize my job) but I'm getting very well acquainted without it.

6. The wall itself is about [redacted] high on the inside. I don't think I'd have a package going into America House compound. However, I could have jumper over that wall and, by detail, all concerned might seem to have legit coverage. On the way in today I noted [redacted] on each corner--one stop side and cement factory side. The militia, of course, gives us complete front of building service.

7. It's almost possible, in my present estimate, and unless I spoil [redacted] routine, rather heavily regimented routing pays off on [redacted] buildings--five in all--that GRUNION landing [redacted] will be a one-time thing. He'll have hands [redacted] the evening [redacted] judgment during the day. No. If this party [redacted] cement factory and foot traffic is heavy, including militia [redacted] it is probably as deadly. Sorry. We'll have to wait until I can give more specific information on my cooling off.

8. Please give my intermediary instructions that he has to get [redacted] to me regularly and I will hand him a blank envelope, which, unless otherwise specified, goes directly to you. [redacted]

9. Didn't dare go down side streets as desired for GRUNION, since, as it turned out I'm the "hottest" thing in town.

10. I may repeat some of this but I'll write another letter as soon as I know I can get it to my intermediary without a delay.

COMPASS

NO COPY RETAINED. GOT TO KEEP IT IN MY HEAD. [illegible]

[redacted] 1 Copy [redacted] 1.3(a)(4)

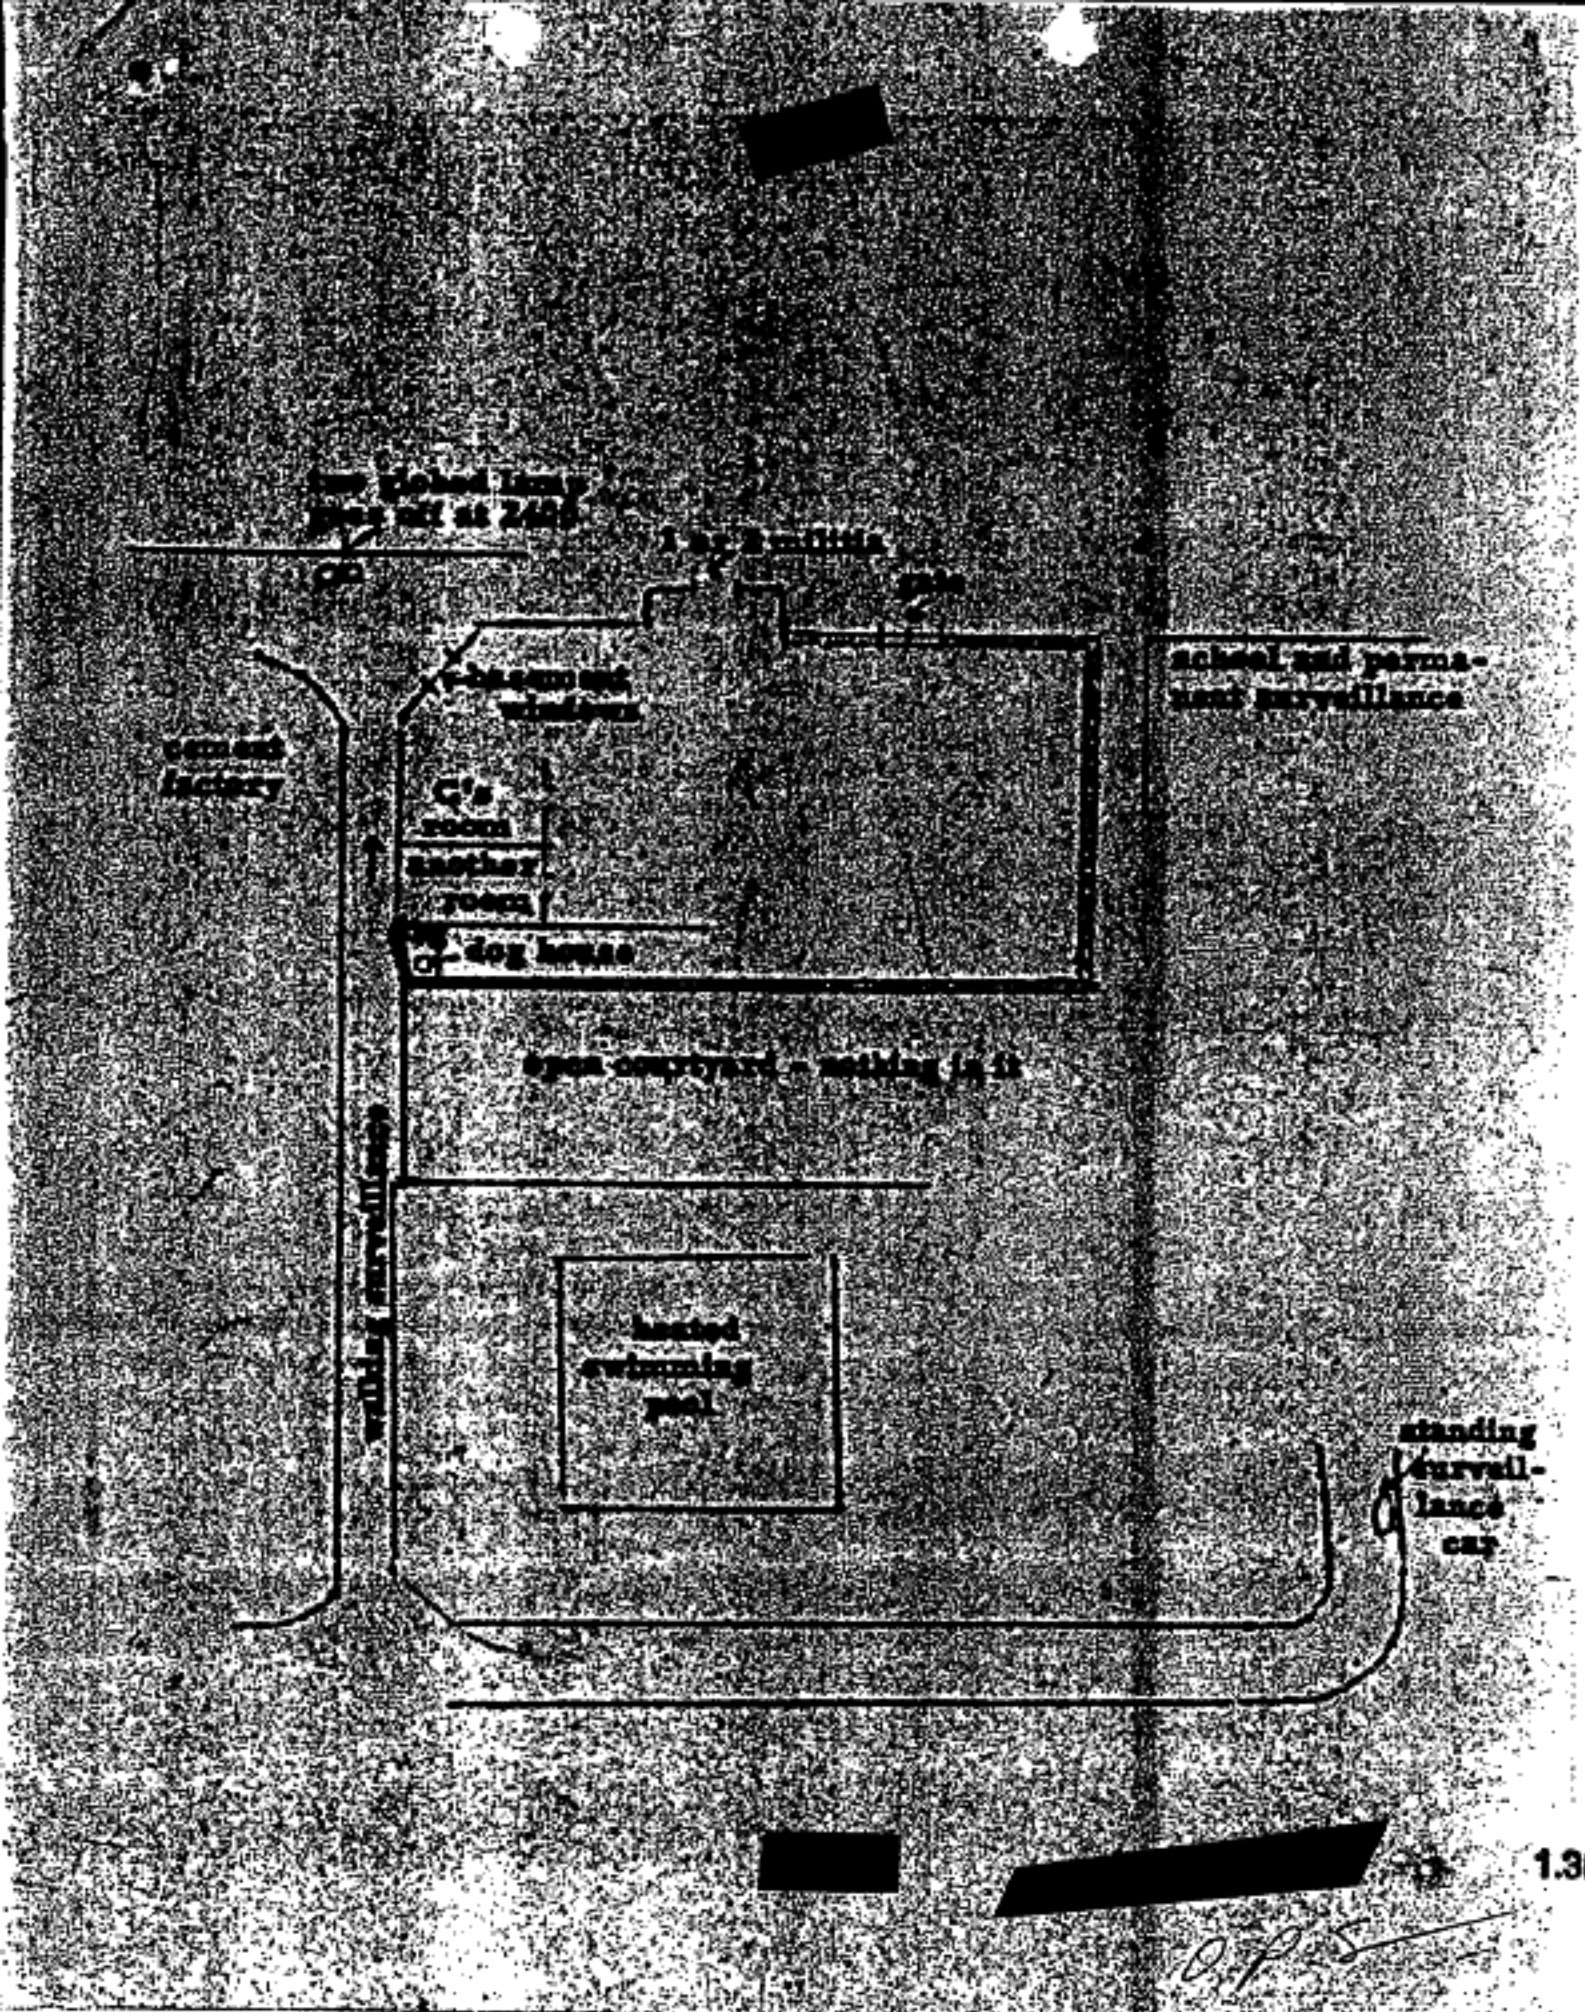
(52)

[redacted] letter No. 2 is a closed gummed envelope. Messages direct 1.3(a)(4)
13 October 1960 [illegible] envelope with scotch tape on the gummed edges.

1. CHISEL remarked on reading COMPASS No. 1 that COMPASS was disturbed at the situation. The word to be used is COMPASS was astounded and somewhat concerned, but not about himself. The America House site for a delivery over the wall is bad but not impossible. The corner of the building across from the cement factory has a window on the basement level facing into the House dining room and COMPASS thinks out of sight of the man at the front door and any other surveillance which might be on the street between the cement factory and the House. There are 3/4 inch bars spaced about six inches apart over the window but it is about three feet from the sidewalk and tossing a package with COMPASS waiting inside is not difficult. [illegible] for [illegible] a few days [illegible] there.

2. COMPASS has not had time or freedom to case either the outside of the house or coverage by our maids and house servants inside. There is the job itself which keeps me occupied because of my fellow worker's lack of coordination. COMPASS is trying to develop organization without stepping on people's feet--coverage by nosy people, vigilant types, and the pros.

3. Oct. 15, 1960. COMPASS will explore stores for housekeeping supplies and will try to get somewhere near the downtown sites even if only for a quick look. COMPASS hopes the weather will be good. If the coverage is as heavy as last Sunday, COMPASS will stay away.



4. Will try to get plans of America House but this is a rough sketch.

5. There is heavy pedestrian traffic in the morning from about seven to eight. They get off the No. 17 bus and walk down the street to take a left to some type of printing and typography shop. I saw it Sunday but have forgotten the details such as names.

6. COMPASS gives the same story of his life to Russ., Amer., and everyone else he meets. His Russian is improving rapidly which may be good or bad. No attempt is made to conceal this at any time, and further all efforts are being made both to Americans and Russ. as to COMPASS' devotion to his work for its own sake and desire to learn to speak Russ. No known problems here.

7. CHISEL delivered your message and is keeping all the material for COMPASS. Access to CHISEL by COMPASS is good. Messages to

[redacted]

Letter No. 5
18 November 1960

Dear COMPASS,

1. Re CHALK. For COMPASS' guidance, SLEDGE is forwarding an operational guide so that COMPASS may benefit from seeing the most important factors inherent in this operation. As COMPASS can well imagine, SLEDGE's shop is under considerable pressure from the top echelons here to get this job done well and very soon. Perhaps, most important, is the necessity for COMPASS to expedite his assigned tasks in order to prevent CHALK from lapsing into dispair and giving up his daily check of the proposed site. As COMPASS is undoubtedly aware, CHALK has been checking the site for over three (3) months and it is possible that his patience and hopes are at low ebb. In addition, SLEDGE's shop must coordinate operational phase II with Ops Phase I, direct AZTEC to a particular city and brief him--all of which must be closely timed with a projected completion date for Ops Phase I. SLEDGE is not criticizing COMPASS' performance but simply is trying to give COMPASS the feel of the situation here--as would be done in our bull sessions were COMPASS here. Therefore, with regard to Operational Phase I, please give this case COMPASS' priority attention, time, brains, imagination, and whatever else it takes. WHEEL must not lose CHALK. If WHEEL does this one well, not only will the wearing of a feather in our hats feel good, but it can have quite an impact in terms of future staffing.

2. With regard to Operational Phase I, enumerated points 1 and 2 are self-explanatory and COMPASS has the detailed casing requirements of these sites included as attachment to WHEEL Letter No. 1. These requirements (in as much detail as possible) should be forwarded at COMPASS' earliest possible time for study and planning at WHEEL. SLEDGE urges COMPASS to make call and case inside of CHALK site as soon as possible.

3. Point 3 of Ops Phase I pertains to the JIG site (or alternate if COMPASS rejects JIG site). SLEDGE appreciates COMPASS' suggestion (bag and string ploy) for use at JIG. However, SLEDGE and company feel that this plan must be rejected because of the psychological effect it more than likely would have on CHALK; the possibility of a citizen strolling along the Naberezhnaya observing CHALK emplacing the packet and the bag being pulled into COMPASS' window; the possible pinpointing of COMPASS as the recipient, and the proximity of COMPASS' room to the Naberezhnaya. With regard to the JIG wall, COMPASS mentioned that the lights usually go on when COMPASS walks into the yard. Does COMPASS turn them on himself or are they turned on by someone else, or do they burn continually at night? Please examine all possibilities of using the wall or window at JIG (or any other JIG possibilities) on a priority basis. With regard to timing, (if JIG site is used) COMPASS should advise as to which evening hour and day of the week he feels is most practical and secure for both COMPASS and CHALK. Also SLEDGE would appreciate receiving from COMPASS an estimated deadline of when COMPASS believes that he can complete all tasks assigned to COMPASS in Operational Phase I. This is necessary so that WHEEL can have lead time to coordinate AZTEC's movements. If COMPASS honestly feels that JIG drops should not be

APPROVED FOR RELEASE
31 MAR 1992

[redacted]

used for security or other reasons, please explain fully the reasons for rejection. WHEEL will abide by COMPASS' decision since he is on the spot and can most accurately gauge the operational situation. If COMPASS rejects the JIG site, then he should, again on a priority basis, locate another drop for CHALK's No. 1 outgoing to WHEEL. Please remember that the reason the wall at JIG was suggested as a site was that, in WHEEL's view, it afforded MAXIMUM SECURITY AND PROTECTION to COMPASS. Therefore, if the JIG site is rejected, COMPASS should keep in mind that his alternate choice should afford maximum security to the unloader (who may be COMPASS).

4. Point 4 of Operational Phase I refers to a drop which COMPASS must locate, sketch and describe so that WHEEL (in letter No. 1) can immediately assign it to CHALK. This will insure a continuity of future commo. In conjunction with this drop, COMPASS should locate a suitable signal site for CHALK to indicate that the drop is loaded and for the unloader to make a counter-signal to assure CHALK that the material has been recovered.

5. Operational Phases II and III are forwarded for COMPASS' information and to round out the total picture of the scope of the operation in its first round.

6. Re dacha area as possible CHALK drop area: WHEEL feels, on the basis of past and current information, that the dacha site and area has little potential for CHALK. It would, of course, take CHALK out of his own locale and possibly expose him as an outsider in a heavily surveilled area. Also the village of Tarasovskaya should not be considered for CHALK since in this small village the residents would immediately recognize him as an outsider and possibly wonder what business brought him to their small village and church. WHEEL will, however, retain and file this drop.

7. Re WHEEL commo to COMPASS and from COMPASS: SLEDGE fully realizes the commo hardships with which COMPASS is confronted and, therefore, previously recommended that, at every secure opportunity, COMPASS refresh his memory with the incoming file held by CHISEL. In addition, to simplify understanding, SLEDGE would prefer to have COMPASS write his letters as succinctly and plainly as possible avoiding any double-talk. SLEDGE has had some initial difficulty in deciphering past correspondence and feels that straight reporting through the secure channel is preferable. Contrarily, if COMPASS is finding difficulty in reading or interpreting WHEEL letters or has any suggestions or criticisms, please let WHEEL know.

8. If SLEDGE and Company can render any support or services of any nature to COMPASS, please do not hesitate to make suggestions.

[redacted]

[redacted]

9. SLEDGE has just received COMPASS' letter of 13 November in which COMPASS made the external casing of CHALK's drop and signal sites. The report is well done and fills a part of points 1 and 2 of Ops Phase I. Keep up the good work, COMPASS!

With best personal wishes,

SLEDGE

P. S. SLEDGE is aware that this letter is rather long and will necessitate COMPASS' concentration. Therefore, SLEDGE suggests that COMPASS might possibly take the letter to JIG for study in the seclusion of his room and return to CHISEL after careful study. COMPASS, of course, can best make this decision.

(60)

[redacted] Vol I

1.3(a)(4)

Letter No. 7
10 January 1961

Dear COMPASS:

This letter is from SLEDGE personally.

In terms of cleaning up the CHALK problem, the following questions must repeat must be answered in order that this operation can get off the ground. WHEEL is considerably concerned that with the passage of time CHALK may get discouraged and discontinue looking for indication from us that we are willing and prepared to cooperate.

1. As concerns the Drop Site that CHALK gave to us to load: COMPASS must actually enter the site area and describe it accurately with narrative and description. Please refer to Letter No. 1 attachments to refresh your memory.

   a. Is the radiator between the two sets of doors or behind the second (inner) set of doors?

   b. How far is the radiator from the doors?

   c. What is the size and shape of the hook? Its thickness and color? How far would the loader have to reach in to fasten the dead drop package on the the hook? Or would it have to be loaded from above rather than from the side?

   d. Is the inside of the building and drop site identical with CHALK's details? If not, where are the discrepancies?

2. As concerns the Signal Site that CHALK gave to us:

   Please review the description as CHALK gave to us; prepare some pretext to actually use the telephone and on one of COMPASS' walks through the area, stop in, make the call, and study the internal set-up to determine if it is actually as CHALK described.

3. As concerns the drop site that WHEEL is to get to CHALK:

   JIG: I still do not understand why specifically COMPASS does not like the wall as a site for CHALK to toss a package over. COMPASS mentioned earlier that the lights in the courtyard go on. Who turns them on? Are they on all night every night? What is the story? If COMPASS has solid objections to using the wall of JIG, then please detail all objections. If COMPASS is determined that JIG cannot be used, then COMPASS must come up with an alternate dead drop site for CHALK to load (which we would unload). Is there any indication that the recent JIG incidents have altered PRESS "protective" and security procedures?

APPROVED FOR RELEASE
31 MAR 1992

4. In order to keep this operation going once initial contact is established, COMPASS must find yet another drop site for CHALK. So please find another drop site which CHALK would lead for another go-around which would afford maximum accessibility and security both to him and to the unloader (probably a diplomatic type or a Redskinner). In connection with this, locate a signal site which CHALK would use to signal and which you would observe on a daily basis while looking for his signal. Both these sites must be fully described in narrative and sketches.

We are truly on the spot as far as the CHALK operation is concerned. I have no alternative now but to ask COMPASS to fulfill the above request within two weeks after receipt, otherwise I shall have to find someone else to do the job. This I would hate to do but will be forced to do unless we have the full package in our hands within two weeks.

I, personally, find reading your letters a little difficult. I, therefore, request that, with our secure means of comms, you avoid double-talk and make your letters as clear and complete as possible. Please prepare them as if they were official despatches. We have found that on some things COMPASS has written, there were several interpretations of what you meant depending on who read the letter.

I wish COMPASS success in this and all future endeavors.

(80)

[redacted] 1.3(a)(4)

[redacted]

[redacted]

No 2709

10 April 1962

14

The following is a translation of the letter which [redacted] passed [redacted] on 28 March 1962, together with 11 rolls of minox film. 1.3(a)(4)

1. 5 January 62, after completing the meeting with [redacted], I turned my attention toward an auto entering the pereulok; violating the traffic regulations, the auto swung around, and one of the men (in the car) was intently looking out. [redacted] had already left. Having waited a couple of minutes, the auto moved off of the pereulok onto Arbatskaya street (the main part) and went to the side of Arbatskaya Ploshchad. In any case I remembered that car. 1.3(a)(4)

12 January 62. I observed no surveillance whatsoever, neither up to, nor after.

19 January 62. After the meeting [redacted] went along Arbatskiy Pereulok down to the side of the Arbat, and, convinced that all was in order with her, I turned from the Pereulok onto Bolshoy Molchanovka and went toward the Arbatskaya Ploshchad. Immediately, as I exited onto Molchanovka, I observed the same car, in which was one man (in a black overcoat). I left without looking for surveillance on me. 1.3(a)(4)

This car: brown colored, No. M Shch - 61-45.

Conclusion:
- Surveillance is being conducted on [redacted], perhaps periodically. 1.3(a)(4)
- It is advisable stop meetings on the street for three or four months,
- [redacted] should continue to behave naturally and at the same time should continue frequenting the shops and the same streets and pereuloks, as in the past, 1.3(a)(4)
- [redacted] should not come out on the street with operational materials - "hooligans" might grab her purse, 1.3(a)(4)
- once or twice a month invite me to small receptions; at American, English or Canadian representatives',
- If something should be important and urgent, then I will transmit it via the dead drop.

2. 19 April. I take off for the U.S.A. for the exhibition "21st Century."

3. Perhaps sometime from the 20th to the end of February I will take off with Gvishiyani to Italy for two weeks, or it is possible that

APPROVED FOR RELEASE
31 MAR 1992

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

on 14 March I will be in Geneva at the Auto Exhibition.

4. I request that a reception be organized for between 10 and 20 February, at which I will inform [redacted] more concretely of all future plans. 1.3(a)(4)

5. In the future at receptions with whom will I be able to talk and pass material, when [redacted] will be absent because of pregnancy? 1.3(a)(4)

6. [redacted] made a good impression, but KRO (Counterintelligence) does not like him and are watching him carefully. 1.3(a)(4)

With warm greetings

Until we meet soon my dear friends

26 January 1962

1. 27 January 1962. - [redacted] was not at [redacted] reception and therefore I have retained all of this until this time.

2. The trip to Italy was postponed until summer, and visit to Geneva in March was cancelled for M.O. (presumably, "by Ministry of Defense") 1.3(a)(4)

3. If all is well then I will take off for the U.S.A. on 19 April. But at the present it's going badly as the KRO are rummaging around concerning my father (kopat'sya vokrug moego ottsa) - they are continually searching for my father's burial place, they cannot find it and therefore they are conjecturing that perhaps my father is alive, and therefore that in the future it would not be suitable to send me on overseas assignments. My command considers these fears meaningless and they are defending me from all these conjectures of the "neighbors." Everything must be decided soon.

4. In March I must meet with [redacted] at a reception and I will pass detailed information about myself and plans for the future depending upon the situation which is in turmoil about me. 1.3(a)(4)

5 March 1962

1. I plan to fly to the U.S.A. on 18 April. Everything is already submitted concerning the visas. The KGB will have its say on the 15th of April. My superiors in the Committee and in the M.O. have made all

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

the arrangements for my trip to the exhibition - "21st Century." If I make the trip, then everything will be alright.

2. If they do not give me permission to make the trip, then my situation will change sharply and become complicated. It will be necessary to leave the Committee, and in the fall of this year, having fulfilled 25 years of service in the army, I will be discharged. We must plan our future work on all of these contingencies of life.

3. If I do not come to the U.S.A., then after the 20th of April it will be necessary to arrange a reception at which I will be able to pass my plans for the future.

MEMORANDUM FOR THE RECORD

SUBJECT: Briefing of Mr. Helms, DDP/COP on New Case

1. This afternoon at 3:30 p.m., Mr. Maury, [redacted] and I saw Mr. Helms on a number of matters. One of them, the new lead from Moscow, was the subject of discussion. I showed him the [redacted] cable from the Ambassador to Hugh Cumming, the letter and contents of the material received from the new lead, and told him of some of the preliminary traces and information about the subject regarding his stay in Turkey and views held by some of his colleagues about him. Also mentioned his selling of jewelry because he needed money and the abortive attempt to sell a camera. 1.3(a)(4)

2. Mr. Helms seemed quite interested in this new lead. He asked what we planned to do. I asked if he would consider utilizing the American Embassy as a point of contact with the Soviet. Mr. Helms replied that it would be a waste of time to negotiate with the Department and the Ambassador, that not only would their response be negative but that many precious weeks would elapse. In the meantime, we could seek another approach to the subject. I suggested then that we could use either a Third National or an American citizen, and asked what his views were in regard to either, [redacted]. Mr. Helms responded that in this particular case, it was worth the risk using either and said if this flapped, we could stand such a flap from the [redacted] He gave me latitude in getting to the subject in any possible way except through the Embassy.

3. Mr. Maury then proceeded to speculate that this new lead might indeed be a provocation, following from the [redacted] case. Before he had gotten too far, Mr. Helms stopped him with a remark that in this point in the Agency's history, we cannot afford but to follow up such a lead.

4. Mr. Helms then inquired if we had informed the WH as yet in regard to the Illegals alleged to be coming to the USA. I said we had not, that we had plenty of time since the particular class in which the Illegals were located would not be graduated until 1963. Mr. Helms said that despite this and on the possibility that a tour at the FDA might be shortened, we must inform the WH immediately. He said further that at this time, the political

APPROVED FOR RELEASE
31 MAR 1992

considerations were such that it might do us some good as an Agency to inform the FBI of such leads. I replied that I would prefer to give the FBI a complete package including all the traces on the Illegals. He agreed, but warned me that this should be done within one month and not in six months. I said "Yes Sir".

5. Mr. Helms further raised the question as to what should be done about the other Illegals going to other countries and then answered his own question that we should not do anything at this time. He warned me however about establishing a tickler system on these leads so that appropriate action could be taken at the appropriate time. I said this would be done.

28 September 1960

MEMORANDUM FOR THE RECORD:

SUBJECT: Contact and Debriefing of Henry Lee COBB on his Meeting with [redacted] in the USSR

JOE BULIK

1. From 1100 to 1500 hours, Sunday, 11 September 1960, [redacted] and the undersigned met with Henry Lee COBB at the SR/9 safehouse for the purpose of debriefing COBB on his contact with [redacted] while in the USSR.

2. COBB stated that he and his friend, COX, left Kiev on Monday evening, 8 August, and arrived in Moscow the morning of 9 August 1960. On Saturday night, 13 August, COBB and COX, who were staying at the BALCHUG Hotel, went to a nearby movie and then walked from the theater to the MOSCOW Restaurant. After eating at the restaurant, the two friends walked through Red Square toward MOSKVORETSKIY MOST. As they were walking on the bridge, and in the dark of the evening, a man [redacted] approached COBB and COX and stated in Russian, "I was on the train with you three or four nights ago from Kiev. You were in a student group in the same car that I was in. There was an agent assigned to watch you. I did not approach you at that time because of the presence of the agent." Continuing along the bridge, accompanied by [redacted] COBB and COX listened intently as he further stated, "At one time I worked in Turkey with the Soviet Embassy. I had a very good friend in the American Embassy, and I have wondered many times what has become of him." COBB characterized [redacted] as being extremely cautious and guarded in his speech and actions. The three walked around the BALCHUG Hotel area and along the Moscow River. When Soviet citizens passed by or approached the group, [redacted] would initiate conversation on innocuous subjects. As they were walking along the Moscow River embankment, [redacted] stated, "I have tried to get in touch with other Americans but so few of them speak Russian. I recognize you as intelligent Americans. I have some information which I wish to give directly to the American Embassy. As a result of this information and our future cooperation, I hope some day to come to the West. I have been carrying this letter with me for about a month. It is only for Mr. FREERS or the Military Attache. Do not open it and don't keep it over-night in your hotel. Go immediately to the American Embassy with this letter. Your Government will be grateful for this information and I may be able to come to the West. I will not give you my name."

[redacted]

APPROVED FOR RELEASE
31 MAR 1992

[redacted]

3. With regard to the U-2, [redacted] stated that it was not shot down at the high altitude that the Soviets claimed. According to COBB, he further said, "Our Air Force was desperate to get the U-2. They tracked it all the way from the frontier, and there were many attempts to bring the U-2 down. We used ground-to-air and air-to-air missiles; even MIG planes were sent out to intercept the U-2. Finally the plane was shot down at a low altitude. In the process we destroyed one of our own MIG planes with ground-to-air missiles." The man urged killing the pilot COX to take this information to the Embassy by word-of-mouth.

4. [redacted] also stated that the RB-47 was not over Soviet territory when shot down. He stated that the RB-47 was definitely over international waters when attacked and crippled. The RB-47 then drifted to "land" and crashed. The walk and conversation with [redacted] lasted from approximately 2300 until 0030. The group broke up two or three blocks from the BALCHUG Hotel and COBB asked COX to take the letter immediately to the Embassy because he did not want to be connected with the incident. According to COX there was but one letter in a plain white envelope. COBB did not then know and does not know now the contents of the letter. 1.3(a)(4)

5. COBB then returned to the BALCHUG Hotel and was asleep when COX returned from the Embassy. COBB believes that COX told him he gave the information and letter to the Military Attache.

6. In describing [redacted] COBB was very uncertain as to his precise physical appearance and felt that he would not be able to identify him if he saw his picture. COBB described the unknown man as being reasonably well dressed, approximately 5' 9", and depicted him as quite nervous. COBB thought that [redacted] said that he was at one time a Communist (or believer), but not now.

7. Even though COBB was most doubtful as to whether he would be able to identify [redacted], [redacted] exhibited a series of Soviet personalities and asked COBB if any of these people were identical with Subject. COBB quickly leafed through the fifteen or so pictures with no apparent success. He then began to study each personality. Upon seeing the 1955 photo of [redacted], he stated immediately that this was the man who had approached them. He was able to make a positive identification.

8. COBB stated that COX had occasion to visit the Embassy on three separate occasions. The first time COX went to have a document notarized. The second time he reported the [redacted] incident in Leningrad. The third time was early Sunday morning, 14 August, in order to deposit [redacted]'s letter at the Embassy as requested.

[redacted]

[redacted]

9. After this incident in Moscow neither COBB nor COX saw [redacted] again nor were they subjected to any unusual provocations or incidents. 1.3(a)(4)

5 October 1960

MEMORANDUM FOR THE RECORD

SUBJECT: Debriefing of Vladimir I. Toumanoff re [redacted]

1. Through the courtesy of Mr. Boster, I had the opportunity of debriefing Toumanoff on 4 October 1960 re his connection with the [redacted] case. Toumanoff said that Bob Owen, who was Acting Chief of Chancery and is normally 1st Secretary and Chief of the Internal Section at the Embassy gave him the two [redacted] envelopes, asked him to read them and be prepared to brief Ed Freers on the contents. Toumanoff said the envelopes were not sealed and they did not have the appearance, as he recalls, of having been torn open. Freers took Toumanoff into the secure room where Toumanoff began briefing him on the contents of the envelopes. Freers interrupted and called [redacted] who came in for the briefing. After Toumanoff gave them a free translation and his comments on the matter, Freers told [redacted] to "take it from there".

2. As far as Toumanoff knows the details of the case, some Soviet military officer gave the envelopes to some tourist with the request that they be taken to the Embassy. He did not know to whom the envelopes were given in the Embassy. He did not know if Bob Owen read the contents. It must be assumed he either did or that he may have been told by Freers of the contents. He said that as far as he knew the Military Attaches in Moscow did not know of the existence of these envelopes.

3. Toumanoff said that he thinks the case could be clean. If the letter had been written six months ago, there would have been no doubt in his mind that they were clean but he feels the time now is ripe for many provocations. On the other hand, he said, because of the disillusionment inside the USSR due to Khrushchev's dumping of the Summit that some people could turn to the USA.

4. He said that a reading of the letter left him with these impressions: that they were written under emotional strain by an able and disciplined mind. The letter does not

APPROVED FOR RELEASE
31 MAR 1992

[redacted]

have the sound of the work of the Soviet police. It had a ring of genuineness. Regarding the technical aspects of the dead drop site and signal site, he said it was a fancy piece of work. He said the author worked out a drop which is inconspicuous and which he feels would be safe to use. He had praise for the neat piece of work.

5. Initially, Toumanoff could not remember any other items in the envelopes beyond the letter and the sites. Then after some recollection he mentioned the photograph; then after more recollection and some prompting he remembered the list of names. He said he did not really study the list -- just noted that the names sounded genuine rather than sounding like pseudonyms adopted for that purpose -- such as Kirov or others which some Soviets like to use. He is of the opinion that this was the listing of military officers going to an espionage school and that possibly they could show up in various Soviet embassies as military attaches.

6. I briefed Toumanoff on the fact that only one officer in the Department, namely Dick Davis, was briefed by us on this matter and I requested that he not speak to anyone about this case without our approval. This he said he understood and would be glad to oblige. I queried him on other leads, which are written separately.

Joseph J. Bulik

JOSEPH J. BULIK

[redacted]

style of readiness to renew contact with the guerrilla unit so that it may serve as a reception committee for another more distant unit.

Immediately after being infiltrated into Cuba, the unit will proceed to conduct numerous recon patrols of the area in which it plans to conduct future operations. Among the numerous objectives of the recon patrols is intelligence relating to:

(1) Enemy methods of operation
(2) Attitude of local inhabitants
(3) Infiltration of the terrain
(4) Current political situation
(5) Current economic conditions
(6) Geographical sketches of enemy lookouts
(7) Enemy capabilities
(8) Presence of friendly guerrilla forces and resistance movements
(9) Health and sanitation data
(10) Natural geographical boundaries
(11) Modes of communication

Once the unit has prepared a working operations map of it's area, it will proceed to gather, prepare, and forward intelligence to the agency concerned.

The unit will continue conducting as many recon patrols or security alerts or until all personnel are completely familiar with the unit's area of operations. If possible, all available local radio sites will be plotted and an airdrop or landing will be made essential prior to conducting local resistance elements. This is to allow the unit to stockpile recon supplies that couldn't be brought in when initially infiltrated. Then, if contact with resistance elements results in betrayal, the unit will have sufficient material if forced to operate as a purely guerrilla column. The duties of the unit when detached as a mobile reception committee are numerous. Primary is the evaluation of the guerrilla unit in question, determine its potential, operational effectiveness, ability to use the supplies requested, and insure their having the receiving factors concerning selection of cadres.

The personnel involved in this operation are native to the area in which they

[redacted] (S NF [redacted]) [redacted]

are to operate. The primary factors being developed concerning this mission are

(1) Transportation and security of the unit while infiltrating Cuba.
(2) The support of this unit once inside Cuba, and the tactical support once they are engaged in decisive operations.

Attached are the following

(1) Detailed list of the materiel that will be used to maintain the unit in operational status.
(2) Detailed description of the training site.
(3) Description of the area in which the unit will operate.
(4) List of the personnel involved in the operation.

[redacted]

The personnel selected for operational training will be transferred by vehicle or aircraft to the [redacted] AIR FORCE BOMBING RANGE, Avon Park, Florida. This area is located approximately 110 air miles South Southwest of the city of Miami, Florida.

Though the entire area is considered a bombing range and under U.S. Government control, only the South Southwest sector of the reservation is used as such. The personnel involved would, of course, be restricted from entering the danger area.

As this is U.S. Government property, civilian personnel do not frequent the area. U.S. Air Force personnel merely tour the sectors not included in the bombing, rocket target area at the S.W. corner of the site. They are restricted from entering that the other sectors due to the lack of even a single footpath. The area is completely inaccessible by motor vehicles.

This area is exceptionally suitable and highly desirable due to the following pertinent factors:

(1) [redacted]
(2) [redacted]
(3) [redacted]

F62-0428/1

MISSION (CONTINUED) [illegible]

(e) Close proximity of civilians.
(f) The area is under control of the U.S. Government, thus anyone observing our personnel in training will assume that they are U.S. Air Force elements undergoing survival training.

Due to the character of this mission, the training site must be secure from civilian observation and it's existence must be maintained [illegible] from all other organizations. To insure secrecy, all personnel will be strictly prohibited from exiting the training area.

CONFIDENTIAL

Moscow, January 13, 1961.

OFFICE MEMORANDUM

Copies to: Charge d'Affaires, Canadian Embassy, Moscow.

Chief, European Division, I.T.R.B., OTTAWA.

Meetings with Mr. Pankovski, State Scientific and Technical Committee

1. Dr. Harrison, Canadian Department of Mines and Technical Surveys, mentioned to the Charge d'Affaires that Mr. Pankovski, of the State Scientific and Technical Committee wished to meet me. Mr. Pankovski replaced Mr. Farmokovsky in mid-November as the "Expert" liaison officer dealing with Canada on matters of exchange of technical missions. As this is our only direct entry and principal contact with this Committee, I was interested to make Mr. Pankovski's acquaintance and arranged that he and Dr. Harrison come to my hotel after work on Monday, January 10. cf — Jck

2. The conversation was quite a general one, ranging over the field of interests between the Committee and Canada and each of our types of work, during which Mr. Pankovski mentioned that for two years (I believe 1956-1958) he had been Assistant and then Military Attache in Turkey, and had been demobilized some eight months ago.

3. On behalf of Mr. Wheeler, President of Ontario Building Materials Ltd., who visited the Soviet Union in 1960, I had officially requested a publication. Mr. Pankovski gave me this publication, at the same time asking that I pass a letter he handed me to a person in the American Embassy. I took the letter thinking it was some innocuous personal note arising out of acquaintance in Turkey, and that the name of the person would be on it.

4. Our meeting was short as Dr. Harrison and Mr. Pankovski had a dinner engagement, and, at Mr. Pankovski's suggestion, arranged that he would come to my hotel for a drink after work on Wednesday, January 11.

5. When I looked at the letter received from Mr. Pankovski it turned out to be a bulky envelope, doubly sealed with tape and without the name of the addressee. I decided to return the envelope to Mr. Pankovski at first opportunity with the explanation that I was in no position to pass over unknown contents to unidentified Americans.

6. On Wednesday at 7 P.M. Mr. Pankovski dropped in and I offered him a drink and a chair, he taking the former, but declining the latter as it faced onto the door, and instead asked if he might sit on a divan on the opposite side of the room. I happened to have the record player on, and in view of this start of proceedings kept it on during Mr. Pankovski's stay.

7. I started the conversation on topics of our mutual interests vis-a-vis the State Scientific and Technical Committee. Mr. Pankovski almost immediately asked whether I had delivered the letter, to which I replied that I had not since I was in no position to deliver unknown contents on behalf of Soviet citizens. He took the letter.

. . . . ./2

APPROVED FOR RELEASE
31 MAR 1992

8. Mr. Pankovski appeared somewhat agitated upon first entrance and never seemed to regain full composure. I tried to cut the trend of conversation and discuss only those matters which came strictly within the realm of his normal liaison function on behalf of the State Scientific and Technical Committee. This was to no avail and Mr. Pankovski persistently reverted to the theme of the importance for him to meet with someone from the U.S. Embassy. I prompted none of his subsequent conversation and throughout tried to emphasize the importance to my position on commercial matters of developing normal relations with the State Scientific and Technical Committee.

9. He said that although he could perhaps understand my action in not undertaking to be a go-between with the Americans, his fate was now in my hands - he hoped I would not inform anyone, (presumably the Soviets). He said he had been trying desperately the last six months to find some way of approaching the Americans, and thought that with his present position in the State Scientific and Technical Committee, Canadian officials would make this possible. He offered to show me the contents of the original letter, which I declined, and said that additional to a document on ballistic missiles, it contained his personal letters to each of President Eisenhower and President-elect Kennedy. He said he had hoped to pass on more documents, thereupon taking out of his pocket a large thickly packed envelope.

10. His determination remained, he said, to contact the Americans to whom he wanted to pass valuable information and that a final objective was to get out of the Soviet Union with his wife and daughter. Almost in passing he mentioned that he was experiencing financial problems.

11. Again he asked that I arrange for him to meet someone from the U.S. Embassy, either through an invitation to the Canadian Embassy, or a luncheon invitation, and if neither of these, that at least I inform the Americans of his interest. He explained his inability to go directly to the U.S. Embassy because of the Soviet police guards, and that even at the State Scientific and Technical Committee it was an almost invariable rule that two Soviets must be present when a foreigner calls. He offered me his home phone number, which I expressed myself willing to have, but suggesting that I would be able to reach him at his office.

12. I declined everything resulting from this one-sided gushing flow, mentioning only that I would hope to be in touch with him at the State Scientific and Technical Committee on our continuing commercial interests. I invited him to stay for dinner but he said he just didn't feel up to it and so ended our 40 minute conversation in English.

13. I am somewhat at a loss to assess the motivations behind these meetings. Mr. Pankovski is about 47, has a pleasant personality and would appear to have reasonable capacity. The rush of events in our brief meetings certainly instilled me with deepest caution. He apparently is the type that has little hesitancy to ask for personal favours as evidenced by his requests to Dr. Harrison for various items from Canada such as salve for eczema, etc., which he assumes Dr. Harrison will send to the Embassy to be passed over. He certainly went into uncalled for detail in our conversations in commenting on matters such as having the record player on, the hazards of phoning his office, repeating that his fate was in my hands, specifically mentioning documents and letters, expressing his regret that apparently I was not quite convinced of his sincerity of purpose in wishing to contact the U.S. Embassy, etc; a partial explanation might be the melodramtic of his previous position as military attache.

. . . . . /3

14. Very obviously his position with the State Scientific and Technical Committee is a minor one, with low salary, and a great come-down from his military career. It is likely that he is a disgruntled citizen.

15. If he is honest in his professed desire to pass information of value to the Americans and have he and his family leave the Soviet Union, he is dangerously talkative. If these are not the motivations, association of Canadian personnel with him, except at the strictest official level, is highly undesirable.

William Van Vliet.

7 June 1961

MEMORANDUM FOR THE RECORD :

SUBJECT : Conversations with Messrs. Ed Proctor and Jack Smith Re Use of CHICKADEE Material in NIE 11-8-61

1. Today Mr. Proctor informed me that USIB, in discussing NIE 11-8-61, did not mention the CHICKADEE report on the Soviet ICBM program. Although the paper had a brief reference to the report in a footnote, it was not mentioned,or even reflected, in the body of the Estimate, and none of the participants at the meeting referred to it. Proctor said he believed this was because even though they probably accepted the CS evaluation of the initial source, they were unwilling to put any weight in the subsource, about whom they knew nothing. Proctor's argument was that no matter how good the source was, since the subsource was unknown to the consumers and was given no evaluation in the dissemination, he would have to be considered "F". The community was unwilling to accord an "F" source any consideration in changing an existing National Estimate.

2. Later in the day I discussed the same matter with Jack Smith who expressed somewhat the same views as Proctor, adding that another factor was simply that the CHICKADEE report did not exactly fit the views of anyone at the meeting.

13 July 1961

MEMORANDUM FOR THE RECORD :

SUBJECT : Assessment of [redacted] 1.3(a)(4)

1. This afternoon Mr. Helms called a meeting of Messrs. Timm, Angleton, and me to consider the [redacted] evaluation of [redacted] 1.3(a)(4) which we received today.

2. We began by showing Mr. Angleton the Berlin report, about which he expressed skepticism. Mr. Helms said he thought we had to be very cautious about "going bail" for any material of such a controversial and significant nature. He said he did not subscribe to the British statement that [redacted] bona fides were clearly established "beyond any reasonable doubt". Mr. Timm expressed similar views. 1.3(a)(4)

3. I said that I agreed we should not go quite as far as the British had gone, but that deception up to now was virtually out of the question. I said the main danger, as I saw it, was that at some point in time, which we could not identify, [redacted] might be apprehended and played back, as [redacted] was. 1.3(a)(4)

4. Mr. Helms said that one of his main concerns was [redacted] personal bias and the possible danger of his "overreading" things he picked up through hearsay. 1.3(a)(4)

5. In conclusion, it was agreed that we would advise Mr. Wisner that we did not go quite as far as the British in accepting [redacted] at face value but had every confidence in him. 1.3(a)(4)

6. Later in the day, Mr. Helms, Angleton, and I went to the Director's office to discuss the [redacted] matter. While we were waiting, we again reviewed the assessment we had made of [redacted] and I showed Mr. Angleton, for the first time, the "source comment" on our dissemination and asked him, in view of his suspicion of deception, how he thought this might serve Soviet purposes. After reading the source comment, he confessed that he could see no way in which it would be to the Soviet interest to give us this line. However, Angleton then took off on the notion that [redacted] was an anarchist or a crank and for some obscure reason was trying to get us in war with the Russians. I frankly do not know what Angleton was talking about 1.3(a)(4)

APPROVED FOR RELEASE

[redacted]

[redacted]

[redacted]

[redacted]

1.3(a)(4)

in this regard and doubt very much that he did.

7. Mr. Angleton left before the Director arrived back from the White House, but Mr. Helms and I reviewed with the Director the British assessment and Wisner's request to brief Ambassador Bruce. The Director agreed that our assessment should be a bit more cautious than the British assessment and authorized us to instruct Wisner to brief Bruce.

25 July 1961

MEMORANDUM FOR THE RECORD:

SUBJECT: Conversations with Mr. Helms by CSR, SR/COP and ACSR/9

1. At noon on 25 July [redacted] were discussed with Mr. Helms. In the ensuing conversation it was pointed out that [redacted] could not be considered for the proposed action task because of his unreliable performance to date and the fact that his judgment and actions appear to be seriously affected by a fear complex. Accordingly it was recommended that [redacted] be utilized for the proposed action task because of his past training, motivation, awareness of surveillance and sound judgment. It was further pointed out that contrary to Mr. Harry S Houston's assumption that [redacted] was under heavy surveillance because he occupied a blown slot, that in fact [redacted] has been reporting very spotty surveillance on only rare occasions. The use of the Doctor for the proposed action task was given secondary preference to the use of [redacted] because the Doctor experiences more surveillance activity, would require extensive training and briefing, might be out of the city on official travel requirements at a crucial moment, and, if utilized, the proposal would require coordination with the Department of Air Force and the Senior Air Attache at the Post.

1.3(a)(4)

1.3(a)(4)

2. Against this background Mr. Helms directed Mr. Maury to see the appropriate Department of State personnel and show them [redacted] and present reasons for our preference for utilizing [redacted] services.

1.3(a)(4)

3. In connection with [redacted] Mr. Helms voiced his considerable displeasure over the fact that [redacted] had been over-sold to him and that henceforth no Agency personnel could be assigned to the Post until a very thorough psychological assessment of them had been made and personally reviewed by Mr. Helms. SR/COP pointed out that just such a program was currently in effect and ACSR/9 commented that wives were to participate in the same assessment program wherever so far possible. CSR asked how far Mr. Helms thought the Agency could go in

1.3(a)(4)

APPROVED FOR RELEASE
31 MAR 1992

[redacted]

[redacted]

this regard. Mr. Helms replied, "We could not force a wife to undergo psychological assessment." He would certainly want to know of any compelling reasons why this could not be done and would evaluate the entire assignment situation should this situation occur. He re-emphasized that every officer regardless of grade or position was to be required to pass a psychological assessment as one of the prerequisites of a Moscow assignment.

4. Mr. Helms directed that [redacted] be recalled from Moscow at the earliest practicable time and stated that he should be separated from the Agency. 1.3(a)(4)

[redacted] 1.3(a)(4)

ACSR/9

Addendum:

Mr. Helms' recommendation concerning [redacted] was subsequently discussed with SR/COP who stated that he had already discussed the matter with CSR and that he agreed that termination of [redacted] was indeed too harsh but that he did not feel the matter could be profitably discussed with Mr. Helms during the meeting and that appropriate recommendations and action would be taken subsequently to retain [redacted]. 1.3(a)(4)

[redacted] [redacted] 1.3(a)(4)

[redacted] 3 August 1961 FN 41+42 Enc. 10

MEMORANDUM FOR THE RECORD :

SUBJECT : Developments re [redacted] 1.3(a)(4)

Set forth chronologically below are several developments re [redacted] some of which will require follow-up action on the part of addressees: 1.3(a)(4)

1. Yesterday (2 August 1961) I authorized ACSI to disseminate certain [redacted] material to EUCOM and USAREUR. I had previously consulted Timm, and we had agreed that we could not dodge this. Today I informed Helms, and he approved. 1.3(a)(4)

2. I talked to [redacted] about the pros and cons of cutting Bohlen in more deeply in the [redacted] case -- in view of the obvious advantage of getting his cooperation in the matter of internal support after [redacted] returns to Moscow. We agreed that if [redacted] comes out again, there might be some advantage in having Bohlen actually meet him, since [redacted] would be flattered by such attention. However, if [redacted] is ever picked up, his having met Bohlen would certainly be an embarrassment to the Department. I later mentioned this possibility to Helms, and he said let's defer consideration of it for the present. 1.3(a)(4)

3. Yesterday afternoon Mr. Helms and I showed Bohlen the [redacted] material of the Vienna meetings. Bohlen reacted enthusiastically, saying it was "terribly exciting" and "the real thing beyond any shadow of a doubt." Bohlen went on to say that the significance of the material lay in: 1.3(a)(4)

a. The extent to which Khrushchev had disseminated it abroad, especially among underdeveloped nations, and

b. The extent to which this dissemination constituted a commitment by Khrushchev from which it would be hard for him to back down.

4. Immediately after reading the material, Bohlen said the Secretary should be informed and went to the Secretary's office to do so. At

APPROVED FOR RELEASE
31 MAR 1992

[redacted] [redacted] 1.3(a)(4)

[redacted] * [redacted]

Helms' instructions, I hurried to intercept the Director before the Secretary was informed. However, I missed connections since the Director was at that moment in the White House. As a result, the Director went to a meeting with the Secretary at four o'clock still unbriefed on the Vienna material, and at the meeting the Secretary mentioned the material to him.

5. Later when the Director met and talked to me, he was incensed and threatened to fire Bissell, Helms, and me. I explained how the situation had come about, assuring him that the Secretary had not gotten a piece of paper, but had only been told briefly of the existence of the material by Bohlen. I also explained to him our fervent efforts to get him before Bohlen got to the Secretary. The Director was entirely pacified and asked for a write-up of the material which he could show the President this morning.

6. When we talked to Bohlen, we obtained from him the very closely held American version of the Vienna talks to aid our translation. I assured him it would be used by only one officer and would be returned promptly.

7. Bohlen also informed Roger Hilsman of the existence of the Vienna material. This morning the Director briefed the President and showed him the Vienna material.

8. The Director later told me that the President was most enthusiastic and would like to be informed, after the transcript is completed, of the extent to which it varies from the American version.

9. This morning I delivered to Bohlen a translation of the decree calling for circulation of the Vienna material among the Communist Parties and the underdeveloped nations. He was pleased, and he said he would also like to have a copy of the Russian text, which we provided him this afternoon. In delivering it, [redacted] strongly emphasized the security aspects of this material. 1.3(a)(4)

10. I also talked to Bohlen today about the British aspect, explaining that the British had the Russian transcripts and were awaiting word from us as to how to handle them. Bohlen said that since the President, Secretary, and top Agency and Department officials have

[redacted]

1.3(a)(4)

now seen the material, he thought we could tell the British that for obvious reasons it was being very closely held in Washington, and we would appreciate their treating it with maximum safeguards on a most limited possible basis. I have asked [redacted] to include this instruction in a cable to London tomorrow. 1.3(a)(4)

11. The Director told me this afternoon he had given one copy of the material on an "eyes only" basis to Sheldon and would show the Director's own copy to Kent. The Director asked what we should do about getting the material to the Defense Department. I suggested that he consult Helms on this and later informed Helms of the foregoing.

12. [redacted] who has been in charge of pulling together for Bissell problems we have had with State Department ambassadors, and has been talking to Roger Hilsman in this connection, tells me that Hilsman has thrown at him [redacted] Thompson's recent agreement for the use of Abidjan. Hilsman argues that this proved that the State Department is always ready to cooperate if we have a legitimate need. I informed Helms of the resulting security implications of this discussion, but he and I agreed that there was nothing we could do about it at this stage. 1.3(a)(4)

13. I received from Oldfield and turned over to [redacted] interesting material from [redacted] about GRU use of a specially equipped automobile. [redacted] will examine this material and recommend the best way of getting it to the Bureau. 1.3(a)(4)

SUBJECT : [redacted] Rear Area Support of Missile Troops in Front Offensive Operations", by Col. Gen. of Artillery G. F. Odintsov

DATE OF INFO: 1961 (Prior to May)

APPRAISAL OF CONTENT : Documentary

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "Rear Area Support of Missile Troops in Front Offensive Operations", written by Col. Gen. of Artillery Georgiy F. Odintsov, Chief of the Military Engineering-Artillery Academy i/n Dzerzhinskiy.

The article appeared in the 1961 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

REAR AREA SUPPORT OF MISSILE TROOPS IN FRONT OFFENSIVE OPERATIONS

by Colonel General of Artillery

G. Odintsov

As is known, timely and thorough rear area supply of missile troops is the most important condition for achieving success in an operation. But the recently adopted system for supplying missiles and missile fuel to troops does not yet completely fit the nature of modern operations. It requires further improvement. From this point of view the article by Lieutenant General M. Novikov is of great and practical interest, and the questions upon which it touched required the most serious attention.

It is difficult, however, to agree with the author's assertion that under present-day conditions the principal organizer of the supply of troops with missiles and .....

[one-half page missing]

The experience of having service of artillery armament subordinate to the deputy commander of troops for the rear area did not prove itself during World War II when the conditions and volume of rear area work were considerably simpler. And it is doubtful that such subordination will be acceptable under present-day conditions. The resubordination (perepodchineniye) of the *service of missile and artillery armament not only increases the volume of work of the rear area chief, but also requires the rear area staff to spend considerable time coordinating both the very important and the routine problems with the directorate or department of missile and artillery armament, the HQ of missile troops and artillery, and also with the departments of the PVO troops of the front (army). It is difficult at this time to state whether it is expedient to have the service of missile and artillery

* sluzhba raketnogo i artilleriyskogo vooruzheniya

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

armament subordinate to the chief of missile troops and artillery, even though such subordination was completely justified in the years of World War II. At that time all of the field and antiaircraft artillery was under the commander of artillery. He organized the combat activity of all artillery, and only he was able to direct the work of the service of artillery armament.

At the present time only units (chast) and large units (soyedineniye) of tactical and operational-tactical missiles, as well as units and large units of field artillery, are subordinate to the chief of missile troops and artillery. Antiaircraft weapons (antiaircraft artillery, troop and army missiles of the class "surface-air") have gone over to the control of the chief of PVO troops of the front (army). The dual control of the combat activity of missile troops and artillery leaves its mark on the conditions of work of the service of missile and artillery armament. It is compelled to execute the instructions and requirements of two chiefs: the chief of missile troops and artillery and the chief of PVO troops. Besides this, the further equipping of combined arms large units and operational groupings (obedineniye) with tanks increased significantly the need for tank ammunition, the expenditure of which is planned and determined to some extent by the staff of the front (army). Consequently, the service of missile armament also has to coordinate its activities with the staff of the front (army). In essence, therefore, three senior officers have an influence on the work of the service of missile and artillery armament in the resolution of basic problems. This is obviously an abnormal situation. In order to eliminate it, it is advisable to transfer the subordination of the service of missile and artillery armament directly to the commander of troops of a front (army).

To some extent this proposal evolves from the real interrelationship of the chief of service with the staff and the commander of troops of a front, since he very frequently is the chief advisor to the command on questions of supplying troops with nuclear weapons and missiles of all types. Also, this proposed resubordination of service brings it nearer to those elements of control where the basic questions of the combat employment of missile troops and other arms of service are decided.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Let us examine some of the author's personal proposals.

The complex utilization of rail, road, and air transport in the operational rear area undoubtedly is necessary, but the possibilities of using them for missile troops are extremely limited. As can be seen in Diagram 1, missiles, component parts, (komplektuyushcheye imushchestvo) and nose sections (golovnaya chast) are delivered from the zone of interior (tyl strany) to the rear area missile bases of the front principally by rail and air. The principal organizer of the loading and dispatch of this freight is the Chief Artillery Directorate and the 12th Chief Directorate of the Ministry of Defense. The responsibilities of the front rear area are limited to dispatching these transports, upon arrival, to the various front rear area missile bases or their sections (otdeleniye). It is unlikely that missiles will be transported within the front area by rail under the existing system of supply because of the extremely limited number of rear area missile installations (uchrezhdeniye) capable of handling missile components and because of the comparatively slow pace of reconstruction of rail lines behind the advancing troops. Besides this, transportation within the front area is also limited, to a certain extent, by the lack of an adequate number of temperature-controlled (izotermicheskiy) railroad cars, specially equipped railroad cars, and gondola cars (poluvagon) at the front.

In the operational rear area the basic method of supplying troops most of the missiles which have undergone preliminary technical preparation is by special cross-country carriers (gruntovaya telezhka) and not just automotive transport. It is practically impossible to use them for other purposes, just as it is not possible in practice to use truck motor pools for transporting missiles. That is why the author's proposal of giving the chief of the rear area the responsibility of transporting missiles to the troops by complex utilization of the transport in the front rear area is impractical; for it does not reflect true capabilities and is not supported from the materiel viewpoint. The only other means that the chief of the rear area will be able to use for transporting missiles is helicopters. But up to the present time they are still considered as resources of the commander of troops of a front and of an army.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

We come to the same conclusions when we analyze the conditions for transporting special fuel and for fueling missiles. It is known that the fueling of missiles is carried out in preliminary preparation areas by forces of the front rear area missile bases. At these preliminary preparation areas the fueling facilities are used both for the transporting of missile fuel and for the fueling of missiles. These same fueling facilities are incorporated in the plan of service of missile and artillery armament for transporting missile fuel elements from the depots of the front. Therefore the principal of function of the service of supply of fuel must be the [one word missing] development of depots and ....

[One-half page missing..]

.... armament, and no other should be responsible for the organization of the delivery of missiles.

The correct deployment and timely movement of rear area missile units of the front and army depend not only on the prepared network of railroad lines and military roads, but also on the groupings of missile troops and on their combat operations. The timely movement of troops is determined by the front troop commander with the active participation of the chief of missile troops and artillery, as well as by the chief of PVO troops. It is evident that these chiefs will not be inactive regarding the deployment and movement of the missile bases of the front rear area. Their thoughts on this subject will be more sound than the proposals of the chief of the rear area. We do not deny the need for a close working relationship among all the above-mentioned senior officers, but we do not see the need to levy this responsibility on the chief of the rear area. The last word concerning this matter will obviously belong to the commander of the troops of a front (army). There is even less need to include the rear area apparatus in the planning of supplying the troops with missiles, when the matters being decided relate not only to the work of rear area missile installations but also to the feasibility of using the transport equipment of units for delivery of missiles. The latter depends, basically, on the missions of the missile units. In other words, the feasibility of using troop transport for delivery of missiles depends on the times of their launching. It appears to us that it is in the interests of this matter to have constant contact between the chief of the rear area

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

and the chief of missile and artillery armament. Regarding coordination, the directorate of missile and artillery armament is required to coordinate with the rear area staff and with the fuel supply service: the areas where front rear area missile bases and missile fuel depots are to be set up; the distribution of the missile fuel received to its destinations; and, the time required to establish *OSG depots and the road network at the front. Under the circumstances the chief of the rear area, although not responsible for supplying the troops with missiles, must give all possible assistance to the service of missile and artillery armament.

We fully share Lt. Gen. M. Novikov's opinion that the new system of supplying troops with missiles has a number of serious shortcomings. In our opinion, to these shortcomings should be added: the narrow specialization of the rear area missile bases of the front and their inadequate ability to withstand enemy action; the difficulty in organizing nose section crews (otdeleniye); the comparatively great distances over which ready (gotovaya) missiles have to be transported; and the difficulty of relocating bases.

According to the data from the troop exercise "Don" the new system provides that each front have one front technical missile base and one front technical ZUR base (Diagram 1). The front technical missile base, which is intended for the preparation of tactical and operational-tactical missiles, includes one transport battalion (parkovyy divizion), one technical, and several mobile technical repair bases. The front technical ZUR base is intended for the preparation of antiaircraft missiles and may be composed of one or two transport battalions and three or four technical battalions. From the front missile bases it is possible to detach two nose section crews comprising a very small personnel force (from the ~~FRTB~~ -- one mobile technical repair base and a transport and technical battery; from the FTB ZUR -- a technical battalion and several transport batteries (batareya).) Because of this, even during a period of preparation for an operation, all missile troops operating in a zone of 150-200 km are obliged to depend on each nose section crew of the rear area base: during the operation all missile troops of a front must depend on each nose section crew of the rear area base. The distances that ready missiles must be transported during different periods of an

* OSG - possibly otdeleniye spetsialnogo goryuchego - special fuel section

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

operation may be 150-200 km, or more. The transporting of ready missiles over such great distances adversely affects their reliability. While retaining the concept of centralized preparation of missiles, it is more advantageous to have two bases with a broad profile but capable of preparing all types of missiles (see Diagram 2), instead of two specialized bases. In this way the distances of transport are reduced by two times and the stability of work at the bases is increased. By organizing the rear area missile bases in this manner, if one directorate of the base is put out of commission it will not affect the work of all sections. In order to reduce the distances that ready missiles are transported and in order to increase the maneuverability of the bases, it is advisable that each base, instead of having specialized sub-units (podrazdeleniye), have small complex rear area installations designed to receive, to relocate, to carry out the preliminary preparation of missiles, and to bring the nose section components (golovnaya chast) to the final stage of readiness. We propose that each rear area missile base have at least two installations for the preparation of operational-tactical missiles and the nose sections of tactical missiles, and also two or three installations for the preparation of army antiaircraft missiles. In our opinion, the proposed organizational structure of the rear area missile bases removes, to a certain extent, the shortcomings of existing bases and insures a wide dispersal of missile resources at all levels of supply. Besides this, it sharply reduces transportation distances, increases maneuverability, simplifies the organization of redeployment, and also increases the stability of the entire system of supplying troops with missiles.

In our opinion, an offensive operation can be started when the missile resources of the front reach 70 - 80 percent of its requirements. The remaining missiles can be on their way to the rear area of the front. Also, it is definitely more advantageous that the troops have in their possession a considerable portion of the missile resources. However, Lt. Gen. M. Novikov's proposal that at least 50 percent of the missiles required for an operation be delivered to the troops before initiating an operation is apparently not altogether correct. This proposal is applicable to a certain extent for tactical and operational-tactical missiles, when the transport capabilities of troop units are fully commensurate with the existing rates of expenditure. Antiaircraft missiles,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

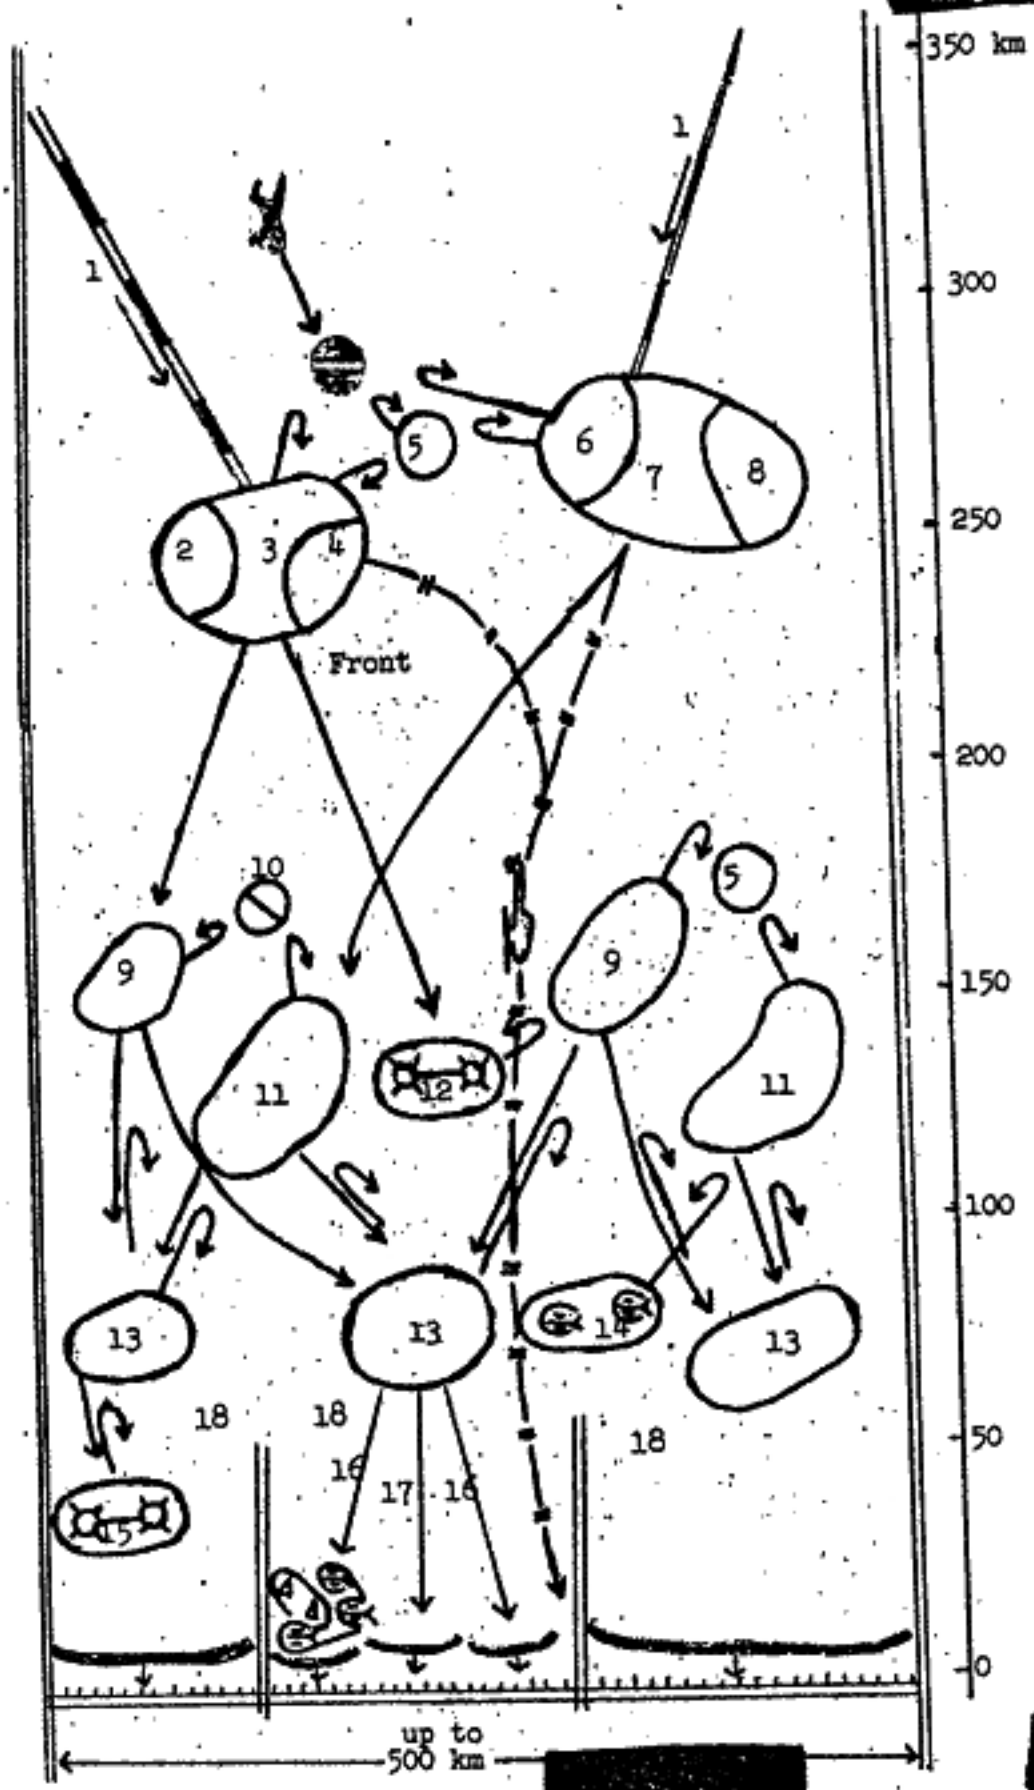
especially those of the army, are expended in much larger quantities than missiles of the surface-to-surface class. Therefore it is doubtful that it will be possible to supply the antiaircraft missile units with 50 percent of the missiles required for the operation in advance of the operation, because the transport facilities of the units are not calculated to handle so great a volume of freight. We think that it would be best to create supplies in the units adequate for two days' needs. Such supplies will become the norms for the mobile reserves of the missile units. The amount calculated for one launching installation (puskovaya ustanovka) may be:

-- Tactical and operational-tactical -- three missiles;

-- Troop antiaircraft (voyskovaya zenitnaya) -- six missiles;

-- Troop army (voyskovaya armeyskaya) -- eight missiles.

Lt. Gen. M. Novikov proposes that small mobile sub-units for storing and transporting missiles be added to the rear of motorized rifle and tank divisions. But why burden the rear of a division if the division will get not more than four to six tactical missiles for the entire operation. The rate of use will be somewhat higher in an antiaircraft missile battalion, but through the joint efforts of the missile and army transport battalions if will be possible to supplement the supply successfully. The addition of a small missile delivery and storage sub-unit to the division rear at once necessitates the addition of at least one lifting crane for trans-loading missiles, and teams to make adjustments (reglamentnaya rabota) on the missile and nuclear nose section. It is clear that this will not increase the maneuverability of the division rear.



Having stated our proposals, we would like to note that the questions mentioned in the article by Lt. Gen. M. Novikov need further serious study, consideration, and testing in troop field exercises.

SUBJECT [redacted] "Anti-Missile Defense of Troops of a Front", by Lt. Gen. V. Mikhaylov

DATE OF INFO: 1961 (Prior to May)

APPRAISAL OF CONTENT : Documentary

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "Anti-Missile Defense of Troops of a Front", written by Lt. Gen. V. Mikhaylov.

This article appeared in the 1961 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

1.3(a)(4)

Anti-Missile Defense of Troops of a Front

by

Lt. Gen. V. Mikhaylov

It is known that at the present time our potential enemies consider missiles as the basic means of delivering nuclear charges to targets. In recent years appropriations in the USA for work in the field of missile technology have increased by fivefold. The success of operations conducted by our front operational groupings (obedineniye) will depend to a significant degree on the number of available means for combating enemy nuclear weapons delivery vehicles, including ballistic missiles.

Combat against ballistic missiles is conducted on the ground and in the air. This article will not take up combat against missiles on the ground. The purpose of this article is to examine the characteristics of ballistic missiles as air targets and to indicate methods of creating appropriate armament and military equipment, and to present a number of principles of organization of anti-missile defense in front operations. In this regard, it is to be borne in mind that initially anti-missile weapons will supplement the existing PVO system of the front; subsequently, depending on the extent to which the potential enemy increases his use of ballistic missiles in operations, it will become necessary to create a system of anti-missile defense which is supplemented by the weapons for combat against piloted aircraft.

As is known, the term ballistic missile is given to a flying object which is controlled only in the initial sector of the trajectory (up to 10 percent of D), which has the appearance of a ballistic curve. Ballistic missiles possess supersonic speeds, various ranges, high trajectories, and different weights of warheads (boyevaya chast). This permits them to be used in strikes against objectives at tactical, operational, and strategic depths. Missiles can carry nuclear charges of different magnitudes (in TNT equivalents of from several thousand to several million tons).

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It should be assumed that operational - tactical designation ballistic missiles can be used against troops and objectives in the front zone. The use of strategic-designation missiles in the front zone can be expected when objectives of a strategic nature are deployed at operational depth or when the conditions of the situation compel the enemy to carry out strikes with these missiles against front targets.

Combat against ballistic missiles can be carried out in the areas of their launch, in the flight trajectory, and also in the sector of their stabilization on entering the dense layers of the atmosphere. Success in combatting ballistic missiles will depend on the tactical-technical data of the anti-missile defense weapons, the system of anti-missile defense created, and the quality of the automated system of control of the anti-missile weapons.

It is known that the employment of means of air attack by the enemy, including ballistic missiles, will be influenced by: the stage of the war, the importance of the theater of combat operations, the enemy capability to use missiles, and the nature of the operations being conducted by the front in a given theater of combat operations.

We shall try to examine, by a concrete example, the quantity and types of missiles the enemy can be expected to use in a front offensive operation in the Western TVD /teatr voyennykh deystviy - theater of combat/.

Let us assume that opposing the front is a group of armies comprising two field armies and a tactical air army. Each field army is reinforced with one group of the URS /upravlyayemyy reaktivnyy snaryad - guided missile/ "Redstone", two to three battalions (divizion) of the URS "Corporal", and six to nine battalions of "Honest John". In the interest of defensive operations for the group of armies one squadron (eskadrilya) of "Thor" missiles carries out one launching by all its installations (ustanovka). Let us also assume that the missile weapons of neighboring field armies are not called upon in the strike against the troops and objectives in the front which we are studying. In this situation the following quantity of ballistic missiles can be employed by the enemy in the front offensive zone (Table 1).

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Table 1

Type of Missile	Number of Sub-Units	Number of Launch Sites per Battery, per Battalion	Number of Missiles in One Launching	Time Required for Reload
Redstone	4 batteries	1	4	5-8 hours
Corporal	4 battalions	2	8	4-6 hours
Honest John	12 battalions reinforced	4	48	0.5-1 hour
	8 mixed battalions from divisions of the first echelon	2	16	up to 3-4 hours
Thor	1 squadron	15	15	8-10 hours
	TOTAL		91 missiles	

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

As can be seen from the table, 91 missiles can be fired simultaneously, of which up to 76 are operational-tactical and up to 15 missiles are of strategic designation. The second firing of ballistic missiles is possible after 3-8 hours, taking into consideration the need to prepare the next firing, to define the targets better, and to change the launching sites (startovaya pozitsiya) for the operational-tactical missiles.

In the event of missile firing at irregular intervals (deliberate firing), which can take place in an operation conducted in a subsequent stage of the war, the number of missiles in a front zone that can be fired in a 24-hour period is only 30-45, of which 25-40 will be directed against objectives in the tactical depth.

Considering the limited number of ballistic missiles at the disposal of a group of armies, it is possible to assume that the strikes of the operational-tactical missiles will be directed against the main formations of front troops, assembly bases for nuclear and missile weapons, and missile large unit and unit positions, control centers, airfields where the frontal air support is based, main railroad junctions, and crossings; the strikes of strategic designation missiles will be directed against the most important rear-area objectives of the front. Strikes by ballistic missiles will be made in conjunction with sorties of piloted aircraft, the launching of balloons, and strikes by winged missiles.

In a defensive operation, the front can repel an attack of a group of armies made up of three field armies and a tactical air army, reinforced with a large quantity of missiles for use in offensive actions. In the zone of defense of a front, as an alternate, the enemy may employ the following number of ballistic missiles (Table 2).

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Table 2

Type of Missile	Number of Sub-Units	Number of Launch Sites per Battery (Battalion)	Number of Missiles in One Launching	Time Required for Reload
Redstone	4 batteries	1	4	5-8 hours
Corporal	6 battalions	2	12	4-6 hours
Honest John	18 battalions reinforced	4	72	from 0.5-one hour
	12 mixed battalions from divisions of the first echelon	2	24	up to 3-4 hours
	Total		112 Missiles	

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

We can see that in a defensive operation a front can expect a greater number of missiles to be launched simultaneously by the enemy than in an offensive operation. The use of nuclear warheads (yadernyye boyepripasy) in all missiles makes it possible to knock out 112 objectives in the defense zone of the front in one launching, 96 of these being within the limits of the tactical zone. Such a strike, naturally, can sharply reduce the defensive stability of the troops, especially in the tactical depth.

In the case of deliberate missile firing, 35 to 55 missiles can be expected in a 24-hour period, of which 30 to 50 will be directed against the most important objectives in the tactical depth of the defense.

The means for anti-missile warfare must be capable of destroying both ballistic missiles with a relatively short range (up to 30 km) and ballistic missiles with a range of from 160 - 300 up to 3,000 km. It is necessary to take into consideration the fact that the short-range missiles will comprise up to 70 percent of all the missiles the enemy will use in the frontal zone.

It is known that the existing PVO means of a front do not have the tactical-technical characteristics to cope with the ballistic missiles of the potential enemies. A radical change is needed in these weapons, especially in the surface-to-air (zenitnaya) guided missiles.

Combat against ballistic missiles in the air requires: an increase in the distance and altitude at which the missile can be detected and tracked by radar; the creation of a guidance system for anti-missiles (sistema navedeniya antiraket), combined with a system of long-range reconnaissance of enemy ballistic missiles and with a system for automatically computing the required data, to insure the interception of enemy ballistic missiles at specified distances and altitudes; the creation of anti-missiles which possess appropriate tactical-technical characteristics; the development of new radiotechnical sets (stantsiya) to jam the guidance and the homing systems (apparatura samonavedeniya) of the ballistic missiles of the enemy.

The combat employment of all these means will be more effective upon the creation of an automated guidance system

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

(avtomatizirovannaya sistema upravleniya) which is based on electronic computing machines (elektronno-vychislitelnaya mashina) and which insures the continuous automatic evaluation of the air situation and the working out of the problem of committing appropriate forces and means of anti-missile combat.

Thus, we view anti-missile combat as a complex system of measures which includes the reconnaissance and assured tracking of ballistic missiles in the air; the automatic computation of the necessary data which will insure the interception of ballistic missiles in the air at specified parameters of the objectives (areas) being covered; the launching of anti-missiles in order to destroy the enemy missiles in the air; radio countermeasures (radioprotivodeystviye) assuring the generation of jamming of the missile guidance system and their homing devices.

In order to effect the timely detection and tracking of ballistic missiles, radar reconnaissance must insure a detection range of not less than 250-500 km in combat with missiles of operational-tactical designation and 2,000 - 2,500 km in combat with missiles of strategic designation.

From the point of view of anti-missile combat, the detection range for missiles should exceed, or at least be equal to, the missile range. However, it is known that any radar station acts only in the limits of direct line of sight. The maximum range of intercept of a radar station located near an objective (group of objectives) being defended, with optimum trajectories, for ballistic missiles with a range of 3,200 km is 2,000 km, and for missiles with a range of 1,600 km it is 1,400 km.

Increasing the height of the antenna does not result in an increase in the detection range. In order to attain an increase in the detection range, it is necessary to move the radar stations away from the objectives (groups of objectives) being defended toward the directions from which strikes by strategic missiles are expected to come. In addition, in order to insure the timely detection of ballistic missiles it is advisable to exploit the new principle of radar-- coherent integration (kogerentnoye integrirovaniye) (random summation) (vyborochnoye summirovaniye), which consists of amplifying the strength of the useful signal (poleznyy signal)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4).

[redacted]

1.3(a)(4)

against the background of fluctuating (local) noises. A radar station, working on this principle, can quickly and correctly determine the distance, speed, and angular coordinates of a moving target within the limits of the line of sight.

According to our calculations, in order to insure the effective use of appropriate weapons (anti-missile), the minimum distance of the boundary of detection of ballistic missiles of operational-tactical designation, with the exception of missiles of the type of Honest John, Corporal, Sergeant, and Blue Water, must be within the limits of 370-620 km, and for missiles of strategic designation, within the limits of 1,420-- 2,100 km.

Taking into consideration the range of ballistic missiles of the Honest John, Corporal, Sergeant, and Blue Water types, as well as the distance of their launching positions from the main line of resistance, it can be assumed that existing radar stations for reconnaissance and target indication will detect these missiles in good time after they are launched. This pertains to missiles having a height of flight trajectory of not less than 4,000--5,000 m. It is imperative that the data obtained be processed automatically and transmitted to the anti-missile weapons in no later than 10-15 sec. for missiles of the Honest John type, and one to two min. for missiles of the Corporal, Sergeant, and Blue Water type.

The necessity for receiving data on the flight of ballistic missiles of operational-tactical designation (such as Pershing and Redstone) with ranges of 370-620 km and on missiles of strategic designation with ranges of 1,420--2,100 km requires that radar stations for reconnaissance have a detection range of up to 500 and 1,000 to 1,500 km, and an altitude capability up to 200 to 800 km. In connection with this, the system of anti-missile combat must have two types of radar stations for reconnaissance in order to assure the system's effectiveness in combating both the operational-tactical and the strategic missiles of the potential enemies.

From the radar stations for reconnaissance of operational-tactical missiles there should be formed: detection centers (uzel obnaruzheniya) consisting of four to six stations with ranges up to 500 km and altitude capabilities up to 300 km; and interception centers (uzel perekhvata) consisting of three to four stations

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

with operational ranges up to 200 km and altitude capabilities up to 150 km. The number of centers will depend on the number of important objectives (groups of objectives) to be defended. The missile detection centers should be connected with the interception centers in a manner which will insure the automatic computation of data necessary for interception and the synchronous transmission of these data to the anti-missile launching sub-units (podrazdeleniye)

The detection and tracking of ballistic missiles of strategic designation should be carried out by special long-range detection centers, having radar stations with an operational range of up to 1,500 km, an altitude capability up to 800 km, and synchronous connections with missile interception centers which have stations with an operational range of up to 300 km and an altitude capability of up to 200 km.

It must be noted that early warning (dalneye obnaruzheniye) of enemy ballistic missiles can be carried out not only during the trajectory of their flight by radar stations with a great range, but also by picking up and amplifying the radio signals which are emitted by the powerful missile engines at the time of their firing. However, this method should only be supplementary (dubliruyushchiy) in the anti-missile combat system organized in a front.

For the detection and interception of strategic missiles the Americans are developing two interconnected systems-- a system of early warning (raneye obnaruzheniye) and a system of interception. The mission of the early warning system is the detection and identification of enemy ballistic missiles, the determination of the approximate trajectory data, and the transmittal of these data to the anti-missile combat means. The mission of the intercept system is the interception and destruction of enemy ballistic missiles at a safe distance from the objectives being defended.

Under simultaneous development are several systems for the interception and destruction of ballistic missiles (Nike-Zeus, Plato, and Wizard). The main system is Nike-Zeus. This system has three types of radar stations: scanning, determination of trajectory, and tracking; the system also includes computers, a tactical control center of the defense area, communication lines, and launching installations (startovaya ustanovka) with Nike-Zeus anti-missiles. The operational procedure of the system is as

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

follows: after receiving the signal from the early warning center, the scanning radar station goes into action first; having a detection range of 1,600 km, it continuously scans (swings) in the direction of the expected attack within a 30° sector. After the target is detected, the station which determines the trajectory goes into operation; this station picks up the target at a distance up to 960 km and tracks it until it obtains precise trajectory data. Each anti-missile battery (batareya) has two radar tracking stations with an operating range up to 320 km; these stations go into operation upon a command from the radar station which determines trajectory. Both stations continuously feed target and anti-missile location data into a computer which, by means of radio commands, guides the anti-missile to the target. During the final phase (uchastok) of the anti-missile flight, the homing system goes into operation and insures the interception of the target.

In order to destroy enemy ballistic missiles in the air, both during the trajectory and as it begins to zero in on the target, anti-missiles are needed which have the tactical-technical characteristics for the reliable interception and destruction of enemy missiles at specified distances in relation to the objectives (troops) being defended. The system of anti-missile launching devices must assure the necessary acceleration before the sustainer engines (marshevyy dvigatel) are ignited, the timely ignition of the sustainer engines, and the accurate guidance and homing of the anti-missiles on the ballistic missiles of the enemy.

It is imperative to have such anti-missiles as would assure the destruction of enemy ballistic missiles regardless of their range, altitude, or speed of flight.

It seems to us that in order to destroy ballistic missiles of the Honest John type it is advisable to employ the troop surface-to-air (zenitnaya) missiles which have been developed. The effectiveness of such missiles has been shown by their range tests (poligonnoye ispytaniye) abroad, particularly in the USA. The deployment of an automated system of interception and its synchronization with the launching system of the troop surface-to-air missiles will provide the combat system needed against missiles of the Honest John type.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

For the destruction of operational-tactical missiles of the Corporal and Pershing type, it is necessary to have an anti-missile with a range of 100-150 km, a speed of not less than 1,000 m/sec, and an altitude capability of 50--100 km. It is advisable that a launching sub-unit for such anti-missiles have 8-10 launching mounts, a duration of firing cycle (tsikl strelby) of three to five minutes, and a preparation time for a repeat firing of not more than 10-15 min. The systems of reconnaissance, of interception, and of the launching of the anti-missiles should be interconnected by means of an automated system based on electronic computers.

To combat enemy ballistic missiles of strategic designation, it is necessary to have anti-missiles with a range on the order of 200-300 km, an altitude capability of not less than 100-200 km, and a speed of 3,000--5,000 m/sec and more. It is desirable that a launching sub-unit of such anti-missiles have not less than 8-10 launching mounts, a duration of firing cycle of not more than 5 min., and a preparation time for a repeat firing of 20-30 minutes. In order to increase the mobility of anti-missile launching installations, it is desirable to install them on railroad mounts, barges, ships, and prime movers with a high degree of roadability.

For anti-missile warheads it is desirable to have both a fragmentation-high explosive type to destroy enemy ballistic missiles in a vacuum (while in free flight trajectory), as well as a type capable of carrying a nuclear charge in order to insure the destruction of missiles during their flight through the dense layers or at the time of entry into the dense layers of the atmosphere (during the phase of stabilization).

Combat against enemy ballistic missiles can be made more effective by creating radio-jamming directed against the missile guidance systems in the initial phase of the trajectory and against the homing device during the final phase of the trajectory. Radio-jamming of the guidance systems of ballistic missiles in the initial phase should prevent the missile from entering its specified trajectory; the radio-jamming of the homing device should deflect the missile from its specified target, but with sufficient deflection to insure the safety of the objective being defended from the explosion of a high-yield nuclear charge. Radio-jamming can be created by special radio-technical jamming sets operating in the same frequency ranges as the guidance and homing systems of ballistic missiles.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Objectives may also be protected from strikes by enemy ballistic missiles by concealing them with radar camouflage (protivo-radiolokatsionnaya maskirovka).

Under present-day conditions, a front, as a rule, will carry out operations in a theater of combat operations in coordination with operational groupings (obedineniye) of other branches of the armed forces. We have already pointed out above that in the front zone of operations we must be ready to combat ballistic missiles of operational-tactical and strategic designation, which will be used by the enemy against objectives in the front zone and against objectives in the deep interior of the country. Within the boundaries of the TVD (teatr voyennykh deystviy - theater of military operations) there should be a single system for the destruction of missiles in the air by the troops in that theater. It appears that the anti-missile defense system in a TVD will consist of the PRO (protivoraketnaya oborona - anti-missile defense) systems of the front and of operational groupings of other branches of the armed forces (the navy, long-range aviation - DA) which are deployed within the boundaries of a given TVD. The anti-missile defense of the zone of interior (tyl strany) will most likely operate in coordination with this system of anti-missile defense.

The anti-missile defense of a front can represent the first echelon of anti-missile defense organized in a given TVD, which, in turn, will be the first echelon of anti-missile defense of the country as a whole.

The task of the front anti-missile defense is to prevent strikes by enemy ballistic missiles against the troops and rear area objectives. As we have indicated above, the front anti-missile defense must include an operational system of special forces and means, intended specifically for combatting enemy ballistic missiles in the air.

Anti-missile defense must be continuous, active, and capable of repelling strikes by enemy ballistic missiles under all circumstances and at any season of the year or time of day.

Anti-missile defense in front operations can be set up according to the principle of defending the most important objectives. This is explained by the fact that at the present time the relatively small amount of ballistic missiles in the enemy's possession limit his use of them to particular objectives (formations of troops). In

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4).

addition, the process of working out the necessary data for anti-missile launchings is relatively simpler when it is related to separate sub-units defending specific objectives. Hence it is possible to set up suitable equipment without a considerable expenditure of materiel.

At the same time, the anti-missile systems being formed on the basis of range for the defense of individual objectives will permit, as we see it, the defense of groups of important objectives (individual zones) in the front zone of action, if the distances between the targets do not exceed the operational range of the anti-missiles, i.e., anti-missile defense can be formed according to a zonal principle.

A front anti-missile defense is organized in close coordination with the anti-missile defense of adjacent fronts (fleets) and of the zone of interior. In organizing a front anti-missile defense, consideration should be given to the character of the operation being carried out by the front; and it should be in conformance with the concept of the operation and with the operational deployment of the troops.

Anti-missile defense can reach its goal when its forces and resources are combined with the measures for the direct protection of troop formations and objectives in the rear area of the front from strikes by ballistic missiles.

In the interests of PRO, all types of reconnaissance should be used to carry out continuous reconnaissance against enemy military industrial plants, supply depots, missile bases, and site locations for missile weapons. This reconnaissance should be organized in the theater of combat operations as well as in the front, both during the planning and the execution of the operation.

During the execution of an operation, the front radar centers for the detection and tracking of enemy ballistic missiles can be located outside the tactical zone, at a distance of not less than 60-80 km from the main line of resistance. Frequently the location of these radar centers may be designated by directives of the High Command (Verkhovnoye glavnokomandovaniye) for the purpose of using the data of these centers for the anti-missile defense of adjacent fronts and the zone of interior in a given theater of combat operations, and, in coastal areas, for the anti-missile defense of the fleet.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The radar posts for control and assurance of intercept by anti-missiles are synchronously connected with the anti-missile launching system and should be located in the areas of the launching sites of the latter.

To protect the more important objectives in the front zone, it will be necessary to detach several anti-missile launching sub-units. The number of these sub-units will be determined by the importance of the objective, its nature and size, and the possible density and duration of the enemy missile strikes.

In defending an objective the anti-missile sub-units can be deployed in a sector (whence the missile attack is expected) in such a manner that their zones of fire will overlap in order to insure the concentration of fire of several anti-missile sub-units in repelling strikes of greater density. The distances between the anti-missile launching sub-units must not exceed the optimum distance needed for the firing of, let us say, three or four anti-missiles on the border of the zones of fire of adjacent sub-units (assuming that the enemy ballistic missile will be destroyed by this number of anti-missiles).

It is advisable to deploy the detached anti-missile sub-units around an objective at a distance which insures the effective interception of ballistic missiles and the control of the anti-missile sub-units by the control points of the anti-missile defense. It cannot be excluded that the anti-missile launching sub-units can be deployed at a distance of 50 - 100 km and more from the objective being defended, which may be determined by the distance of the approach of the missile to the objective, by the dimensions of the internal borders of the zone of fire of the anti-missile sub-unit, and the feasible distance from the control point of anti-missile defense (depending on the range of radiosynchronous transmission).

If several important objectives within the limits of a theater of combat operations are in close proximity to each other, a zonal defense can be created for their protection.

It would be advisable to deploy those anti-missile launching sub-units detached for zonal defense purposes in a sector from which the enemy ballistic missile strike is most likely to come; and they should be deployed in several rows (two or three) in such

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

a manner that the zones of fire of these sub-units will overlap. The dense overlapping of the zones of fire of these anti-missile sub-units creates conditions for repelling a concentrated missile attack from the most likely direction, and it allows for the destruction of enemy missiles in the dead zones of adjacent anti-missile sub-units.

The total number of anti-missile launching sub-units needed by a front will depend, on the one hand, on the number of ballistic missiles which the enemy is able to use against objectives within the front zone and, on the other hand, on the probability of destruction of each missile by the weapons of the PRO. We must also take into consideration the maximum number of missiles the enemy can fire in a simultaneous launching. There should be a sufficient number of anti-missile launching sub-units in a front to insure the certain destruction of all ballistic missiles launched simultaneously by the enemy against front objectives or those flying over the front zone in the direction of the zone of interior.

If we calculate that four or five anti-missiles are needed to destroy one ballistic missile (according to American data 8-10 anti-missiles are needed to destroy one ballistic missile), then a front, according to our previously stated examples (see Tables 1 and 2), may have to launch the following in a 24-hour period:

-- in an offensive operation, up to (4-5) X (15-27) = 60-135 anti-missiles (combat against ballistic missiles of the Honest John type will be conducted principally by carrying out strikes against enemy site locations and assembly bases; in the air it will be conducted by surface-to-air missile units of the PVO system).

-- in defensive operations, up to (4-5) X 16 = 64-80 anti-missiles.

The indicated number of anti-missiles used in rapid fire by anti-missile sub-units, 15-20 launchings in a 24-hour period, can be launched by four to seven launching sub-units in an offensive operation and by four or five in a defensive operation. This number of anti-missile launching sub-units thereby makes up the necessary strength of a front.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In view of the fact that a front system of anti-missile defense will be coordinated with the anti-missile defense systems of adjacent fronts and of the zone of interior, the number of anti-missile launching sub-units in a front can be decreased accordingly.

In the event that the missile strikes against objectives in the front zone are carried out in greater density, it will be necessary to increase the number of anti-missile sub-units.

The system of anti-missile defense in front operations initially can consist of several formations of the means of anti-missile combat:

-- formations of the means of combat against missiles of operational-tactical designation with a range of 50 to 100 km and speeds up to 1,000 m/sec; in our opinion, this formation can consist of PVO surface-to-air missile units which have new missile systems capable of destroying the above-mentioned missiles of the enemy;

-- formations of means of combat against missiles of operational-tactical designation with a range of 100 to 1,000 km and speeds of 3,000 m/sec and above;

-- formations of means of combat against missiles of strategic designation.

The development and refinement of missile and electronic technology will, evidently, increase the possibilities for the creation of a universal defense system which will insure effective combat against missiles of the most varied designations. Furthermore, this system will actually encompass combat against all enemy means of air attack, including piloted aircraft.

The successful combat against ballistic missiles in a front requires the organization of close communication between the means of reconnaissance and tracking of enemy missiles and the systems of anti-missile launching. The best way to achieve this close communication is to combine them into a single troop entity.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In our opinion, it would be desirable for a front to have an anti-missile brigade or regiment comprising several sub-units (three or four) for the detection and tracking of ballistic missiles, several anti-missile sub-units (five or seven), and several sub-units for radio-countermeasures [radioprotivodeystviye] (four -- five); all of these sub-units would be interconnected during combat by an automated system based on electronic computers. This brigade or regiment should be subordinate to the commander of front air defense troops.

As we have already indicated above, as the number of anti-missile units of a front increases, the existing PVO system will gradually grow into a system of PRO, headed by the chief of PRO troops.

Inasmuch as it is too difficult for a front to organize reconnaissance of the guidance systems of ballistic missiles of strategic designation during the initial phase of their trajectory, it would be advantageous, during front operations, to set up jamming principally directed against the homing devices of enemy missiles, in order to prevent them from homing in on their programmed objectives. It is advisable to locate the jamming sub-units in the directions of the probable flight of enemy ballistic missiles, on the approaches to the more important targets of the front zone, at distances which would assure reliable detection and the subsequent neutralization of the homing devices of the ballistic missiles.

The anti-missile defense system in front operations can be effective only if there is developed an expedient control system for the means which participate in combating enemy ballistic missiles. We believe that the control of the means of anti-missile defense can be centralized on the scale of a theater of combat operations for the destruction of missiles of strategic designation, on the scale of a front for the destruction of missiles of operational-tactical designation with ranges up to 1,000 km, and on the scale of an army for the destruction of missiles with ranges up to 50--100 km.

Thus, in order to insure success in combatting enemy ballistic missiles, it is necessary:

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

-- to work out the following technical means of combat in a short period of time: radar stations for the early warning and tracking of ballistic missiles in the air; radar stations for controlling the anti-missiles; a system of automated control of all the means of anti-missile combat; various types of anti-missiles and stations for jamming the guidance systems and homing devices of ballistic missiles.

-- to supplement the present PVO system with means of combating enemy ballistic missiles and subordinating these means to the chief of front PVO troops; subsequently, to work out a unified system of combating the air enemy, which would include combating ballistic and cruise missiles (krylataya) and piloted aircraft on the scale of a front and which would operate in coordination with similar systems in adjacent fronts and in the zone of interior; considering that the principal means of air attack in the future will be missiles of various designations, such a system of combat can be called an anti-missile defense system;

-- to control the means of anti-missile combat from a control point of front PVO whenever these means are supplementing a front PVO system; upon the creation of an anti-missile defense system, it will be possible to control the means of this system from special control points organized in a front and, sometimes, in a theater of combat operations.

SUBJECT : "The Missions of the Navy and Methods of Carrying Them Out", by Admiral V. Platonov

DATE OF INFO: 1961 (Prior to May)

APPRAISAL OF CONTENT : Documentary

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "The Missions of the Navy and Methods of Carrying Them Out", written by Admiral Vasiliy I. Platonov.

The article appeared in the 1961 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

The Missions of the Navy and The Methods of Carrying Them Out

by

Admiral V. Platonov

New weapons quite naturally compel a review of the paths of development of the types of armed forces and the methods of using these types of armed forces in a war. At present, obsolete combat equipment and armament is being vigorously forced out by new types of weapons and military technology. Tube artillery on the sea, bomber aviation, and large surface vessels have irrevocably lost their former significance. However, all this does not provide any basis for reducing the missions of our Navy merely to the destruction of vessels carrying missile-nuclear weapns (raketno-yadernoye oruzhiye) at sea, as proposed by Colonel General Gastilovich in his article (Spetsialnyy sbornik statey zhurnala "Voyennaya Mysl", First Edition, 1960).

If we proceed from the fact that a modern war will not be a blitzkrieg, but will be lengthy in nature, we unavoidably come to the conclusion that there will be a wider scale of combat operations by naval forces. It is necessary to assume that the known forms of combat at sea will undergo changes, and that new methods of naval operational art and tactics will be introduced, while accomplishing both the old and the completely new missions of the Navy.

The destruction of aircraft carrier attack large units (avianosnoye udarnoye soyedineniye) is one of the most important missions of the Navy. Since aircraft carriers are for the present still the main delivery vehicles of enemy missile-nuclear weapons at sea, naturally they must be sunk first. Unfortunately, the means and methods of accomplishing such a highly difficult mission are often oversimplified. It is reckoned that, having decided to put our bases out of operation or destroy our industrial centers, an enemy aircraft carrier attack large unit would sail out into the open sea, approach Soviet shores to the distance of the radius of its aviation, and launch its planes,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

which would deliver the attack. Meanwhile, our submarines, deployed in advance in the area of operation of the aircraft carriers, and aided by reconnaissance and attack aviation, would sally forth to the attack and, using massed actions, would sink the enemy vessels. The training exercise carried out by the Pacific Fleet in October 1959 was conceived and oversimplified just this artlessly and sketchily.

It should be assumed that even the most untrained fleet will not act in such a primitive and imprudent manner. Where it is permitted by the conditions of the theater, the enemy will use, in the first instance, aviation from his coastal airfields and land missile units for attacks on objectives of our seacoast. In the areas where aircraft carrier attack large units will operate, they will use for their concealment and protection suitable anchorages of bays and straits, equipped with naval bases. Such possibilities actually exist in all of our sea theaters. Furthermore, if the situation forces the enemy to sally forth into the open sea to deliver an attack, the aircraft carrier attack large unit will see to it that a thorough search is carried out and the area of its maneuvering is cleared of enemy submarines.

Consequently, an encounter and battle of our forces at sea with a freely maneuvering aircraft carrier attack large unit in sight of our seacoast must be considered unlikely, and the mastering of such a simple mission must be considered as not achieving training goals.

The matter is even more complicated in remote areas of the ocean, on the lines of communication of the enemy. There, aircraft carrier attack large units can act solely as protective forces for convoys or as antisubmarine (PLO) hunter-killer groups (poiskovo-udarnaya gruppa). They will persistently hunt our submarines and attack them first. The strikes of the submarines will have the character of counterattacks and will follow only after warding off the active operations by the forces and weapons of the enemy PLO, after breaking through or bypassing the immediate protection of the aircraft carriers. This means that no matter what formations and combat order the submarines adopt, all of them will be intermingled at the moment of delivering the strike on the main objective.

Thus, combat against aircraft carrier attack large units at sea is only part, albeit the most difficult part, of the mission of destroying the ocean communications lines of the enemy.

[redacted]

1.3(a)(4)

Thus, the operational-strategic command-staff training exercise conducted by several of our fleets in the Atlantic in August 1960, in which submarines operated similarly against a freely maneuvering aircraft carrier attack large unit, can be justified, if only as a first endeavor at breaking out into the ocean.

The complexity of preparing and carrying out operations designed to destroy aircraft carrier attack large units urgently requires the correct selection of the main forces for accomplishing this mission. An over-all appraisal of the various qualities of all of the combat means of the Navy shows that only submarines, employed in coordination with aviation, can serve as such forces. And just when it seemed that this course of action had become potently clear to everyone, Rear Admiral V. Bogolepov comes out in print with (Spetsialnyy sbornik statey zhurnala "Voyennaya Mysl", Third Edition, 1960), the unfounded assertion that the main force in combating aircraft carrier attack large units is aviation.

Without burrowing into the details to prove the unsoundness of this strange conclusion, we point out only that means of combat are usually chosen not on the basis of their monetary cost, as Rear Admiral V. Bogolepov does, but on the basis of their degree of reliability in accomplishing a mission assigned to the armed forces. It is self-evident that aviation supplied with missile weapons is a powerful means of carrying out combat operations at sea. However, it should be taken into account that before it can carry out combat missions it must fly to the Atlantic Ocean for a look at the enemy. While aviation is considerably more maneuverable than submarines, it is inferior to submarines in radius of operation, in concealment of deployment and approach to the enemy, in endurance or duration of staying in position, in capability for repeated attacks, in viability, in potential for self-defense and evasion of enemy attacks, and in ability to operate irrespective of weather conditons and the time of day. On the basis of exactly these qualities of firmly insuring reliable fulfillment of the basic missions of combat at sea, submarines are indeed in the category of the main forces of the Navy. Naval long-range aviation is the combat assistant to submarine forces. It protects their operations at sea and coordinates with them in strikes.

Rear Admiral V. Bogolepov predicts a great future for atomic aviation in operations at sea. One should not give oneself up to illusions. Even though it may be too soon to argue about what the atomic engine will do for the airplane, it is still possible to say

[redacted]

1.3(a)(4)

now with certainty that such a plane will be shot down by the weapons of antiaircraft defense (PVO) just like all its piston-engine and jet predecessors. As for new speeds and unlimited radius of operation, it seems that these factors have been exhausted by pre-atomic piloted aviation and will be limited in the future not so much by technical improvements in aircraft engines as by the endurance of the human organism.

Speaking of the future of aircraft carrier attack large units, it should be noted that, in general, they have had their day. This is so as a consequence of the fact that the aircraft carrier has become too easy a target for missile weapons. Its loss creates a large gap in the combat formations of the navy. The aviation carried by an aircraft carrier is easily shot down by surface-to-air (zenitnaya) guided missiles, and is no longer capable of discovering submarines at sea so long as they do not appear on the surface. Aircraft carrier attack aviation is more and more being replaced by missiles, and hunter aircraft by antisubmarine vessels. Aircraft carriers are clearly being supplanted by missile-carrying submarines, PLO submarines, and corvettes having good means of search, antiaircraft missiles, depth charges, and antisubmarine missiles (protivolodochnaya raketa).

Combat against missile-carrying submarines. The unwieldy structure of combat formations of aircraft carrier attack forces, the great vulnerability of aircraft carriers, the impossibility of concealing their movement, and the unreliability of aerial attacks against coastal objectives, is forcing the navies of the NATO countries to shift the task of operations against the coasts from aircraft carriers to missile-carrying submarines.

The advantages of missile-carrying submarines over surface aircraft carriers is so obvious and overwhelming, and the rate of construction of submarines by our potential enemies so serious, that the danger of missile attacks from under the sea is becoming quite real. The threat of missile-carrying submarines is marked by the peculiarity that it concerns not only our naval bases, ports, and seacoast, but also industrial centers deep inside the country. Therefore, combat against enemy submarines and their missiles goes beyond the bounds of the missions and capabilities of the Navy and must be carried out by both the forces of the fleets and troops of the PVO of the Country.

Many people assume that with the start of a war it will be sufficient to deliver a strike by intercontinental (mezhkontinentalnaya) missiles upon the submarine bases and shipyards of the aggressor in

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

order to put an end to his Polaris carriers. However, our enemies are assuredly considering such a possibility. They are making preparations to move their submarines out from under a nuclear strike, deploy them at sea beforehand, and then to repair and supply them at temporary basing points concealed in unequipped bays or located on surface or submarine tenders, and at mobile rear area stations mounted on automotive vehicles. Missile-carrying submarines are capable not only of delivering the first nuclear strike, but also of continuing the war until they are all destroyed.

A careful analysis of our existing methods of combating missile-carrying submarines shows that their means is not notable for its originality. In one case these methods proceed from the assumption that enemy missile carriers (raketonosets) will come into our closed seas and that then the tactics of destroying them will in no way differ from the long-known methods of combating the old submarines operating near the seacoast. Some comrades think that missile-carrying submarines will approach our coasts from the spacious open sea to a point within range of their Polaris missiles and open fire upon the continent. In this case, combating them will differ from the usual methods of protecting our communications lines only in the degree of remoteness of the operations from bases. Sometimes the combating of missile-carrying submarines is related to the missions of the PLO of a protected area of a base, the methods of which have not changed from the time of World War II (Velikaya Otechestvennaya voyna).

Strictly speaking, we do not yet have finalized methods for combating missile-carrying submarines. Even the main forces for accomplishing this mission have not been defined. Rear Admiral V. Bogolepov, for example, in analyzing historical experience, tries to prove that, not only in the past, but also in the forseeable future, the main force for combating submarines is aviation.

Combat against submarines really has its own history. In World War I, submarines possessed insignificant endurance, causing them to operate mainly near the seacoast and on the approaches to ports and bases, where the sea supply routes meet. At that time aviation had just been born; therefore, the only means of combating the submarine threat was the surface vessel. The enemy was detected with the naked eye and sunk by ramming, with artillery shells, and with depth charges. During World War II, in spite of a sharp increase in their endurance, submarines continued to travel on the surface, to surface for charging batteries, and to carry out attacks at periscope depth. In essence

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the submarine remained a semi-surface vessel as previously and was observed visually. This circumstance facilitated the hunting of submarines by aviation, which, possessing a large apparent horizon and high maneuverability, soon became the main PLO force, the grave-digger of submarines.

The modern atomic submarine is another matter. In general, it can stay below the surface of the water for the entire duration of an operation. Hidden in the ice of the Arctic, in the fiords of Norway, or among the islands of the Aegean Sea, atomic submarines will deliver missile fire on our territory. Possessing underwater speeds which are not inferior to the speeds of the fastest surface vessels, they are capable of escaping from the attacks by PLO weapons at great depths and of evading pursuit. Under these conditions one asks what results can be expected of hunter-killer antisubmarine groups composed of aviation and surface vessels? None. And helicopters, with their insignificant radii of operations and their inability to fly over the sea in poor visibility, at night, and in bad weather, will also be completely useless here.

Antisubmarine submarines armed with the most improved sonar (gidrolokatsionnaya) and hydroacoustic (gidroakusticheskaya) equipment can be the only real forces for combating missile-carrying submarines. Underwater sonar search, underwater patrolling, and underwater patrols and ambushes must become their tactical methods. Active combating of missile-carrying submarines and all maneuvering connected with hunting and destroying them must now be carried on deeply underwater instead of on the surface. There is no other way.

Unfortunately, our military press has not yet devoted much attention to working out methods of combating missile-carrying submarines. In those few articles in which these problems are treated, PLO submarines are assigned the limited mission of detecting the enemy in narrows and at the exits from his bases.

Combat against ocean shipping. Without touching upon the well-known questions of the importance and significance to the European countries and to the United States of ocean lines of communications, we will only point out that this shipping will not cease even after all the naval bases and commercial ports of the warring nations have been destroyed by missile-nuclear weapons strikes. The landing of the Allies in Normandy in June 1944 has already shown in what short periods of time it is possible to create immense temporary port

[redacted]

1.3(a)(4)

installations from sunken ships. The new capabilities of industry and construction technology now make it possible in the course of one night to install towed and self-propelled pontoon wharves on an unequipped shore, to build artificial harbors, and to carry out roadstead loading of tankers and dry cargo vessels. Consequently, the destruction of ports can cause only a temporary delay of shipping and nothing more. The main burden of the operations for the destruction of shipping, particularly the destruction of convoys, must be transferred to the open ocean.

The content of the combat preparedness of the navies of the countries of the aggressive military blocs shows that in the waging of combat by our forces against ocean lines of communications, the first question that should be examined is that of the main strike and the primary objective of the attacks. If, previously, the main strike against convoys was directed against cargo transports and large surface vessels, such a course of action is now unacceptable. The combat formations of aircraft carrier strike forces have come to be formed in such a manner that it is impossible for either our submarines or aviation to approach the transports without a fight. Not many forces will succeed in circumventing the dense PLO screens and the circular lines of protection. Therefore, it becomes necessary to choose the aircraft carriers as the main objective in combat against enemy shipping. Transports must become the objective of attacks during the successful development of the operation for the destruction of convoys. Naturally, the new missile-nuclear weapons should be used in the main strike and old weapons can be used to exploit the success of the strike.

One cannot assume that the existing system of convoys will remain unchanged. As soon as this system ceases to satisfy the requirements of security and reliability for shipping, it will be replaced by a new system. What form the protection of transports on the ocean may take will depend on many factors, but to some extent World War II has already provided a new structure of convoys. In the Northern Theater, German transports with little advance protection moved along the Norwegian coast, covering one side by staying close to the shore and protecting the other side with an antisubmarine mine barrier. It must be said that such an unexpected measure introduced great difficulties into the operations of our submariners. It should be assumed that the complexity of combating atomic submarines with maneuverable forces will lead to the wide use against them of fixed means of combat facilities (pozitsionnoye sredstvo borby) and of jamming of their observation and control /facilities/.

[redacted]

1.3(a)(4)

One may often hear arguments that the movements of personnel and urgently needed cargoes will be effected by aircraft, naval vessels, and even submarines. All this has had its place in the past, and possibly may have its place in the future, but such shipments can only be incidental in nature. They will neither replace nor eliminate the need for large-scale use of maritime cargo transports.

An important and still unresolved problem in combat operations on the lines of communication is the question of the attacking submarines' obtaining accurate data on the movements of the target. The gap between the means of target indication, paralyzed to a virtual standstill, and the technology of submarine construction, which has moved far forward, existed even earlier and is constantly increasing. The submarine long ago became capable of firing from underwater, but in order to obtain firing data it must come to the surface as before or must approach submerged to within risky distances of the enemy. Such use of new large atomic submarines is intolerable. Without waiting for the time when accurate data on the location of the enemy may be obtained by means of artificial earth satellites, our scientific research establishments must take steps at once to eliminate this lag which was permitted to develop, and achieve an increase in the distance of underwater observation (nablyudeniye) and in the accuracy of underwater direction finding (pelengovaniye).

In delivering strikes against enemy convoys, submarines can use missiles and torpedoes. In attacks against aircraft carriers, one must obviously give preference to guided missiles, since they are superior to torpedoes in both range and speed. Even though a missile salvo from an underwater launching reveals the missile-carrying submarine, whereas a bearing cannot be taken on the path of a torpedo, it is necessary none the less to disregard that advantage of the old, slow-moving weapon.

There is no need to expend missiles against transports, since one or two ordinary torpedoes are sufficient to sink a merchant vessel.

An analysis of the conditions of modern naval combat shows that it will apparently be difficult to find a use for torpedoes with atomic warheads, including even long-range torpedoes.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

As can be seen, the existing missiles and torpedoes have shortcomings in their use against vessels by submarines. Therefore, it is necessary to make greater efforts in perfecting a submarine missile (podvodnaya raketa), from which there is every reason to expect hopeful results.

Combined operations. The predominately continental character of our country has always determined the relatively unimportant place which combined operations of the Navy with other types of armed forces have previously occupied in the wars of the Soviet Union. At the present time, the situation in this respect is changing.

We shall dwell briefly on the problems of repelling and of debarking strategic landing forces and on the participation of submarines in delivering strikes against enemy coastal objectives.

The debarking of large landing forces for the purpose of opening a new combat front or of transferring combat operations to other continents has been practiced sufficiently often in past wars. As a rule, debarking operations have succeeded, since the initiative in the selection of the time, place, and forces belonged to the attackers. However, the success of the operations of the landing forces on shore depended on the quality of preparedness of the forces, the weapons of the anti-landing defense (protivodesantnaya oborona), and the ability of the defending side to bring reserves to the area of the initial attack and to mobilize internal resources. The latter have always existed in a country well prepared for war. Thus, the well-known, successfully initiated Dardanelles landing operation of the British and French in 1915 was not exploited on shore, and the brilliantly executed debarking at Normandy in 1944 nearly ended in catastrophe when the Germans broke through the front of the Allies with their tank armies in the Ardennes in December 1944, and that happened when fascist Germany was barely able to stand on its feet, only a few months before its downfall! Considering the above, one must regard the debarking of significant forces by our potential enemies on the territory of the Soviet Union as unlikely at the present time.

The possibility and necessity of the debarking of strategic landing forces by our Navy evolves from the liberating mission which the Soviet armed forces are called upon to serve. It is naive to expect that the third world war will be limited to the European continent, that the liberation of Europe alone will lead to the downfall of the entire imperialist camp and that it will only be

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

necessary to drop some hydrogen bombs on it with no need to land troops on the shores of island or transoceanic countries. On the basis of the experience of World War II, it is known that it is only possible to deal the final blow to an aggressor in his own den. Inasmuch as aggression in a modern war is likely to be from beyond the sea or ocean, it is only possible to reach its nest for the final blow by means of a naval landing operation. It is natural to assume that such a landing must be composed of several armies, that thousands of ships and naval vessels will be needed for its landing, supply, and reinforcement, and that it will be necessary to precede the operation itself by successful operations to achieve air and sea superiority. But it is certainly necessary to prepare for such an operation, the more so because recently we have completely, and without reason, lost interst in the debarking of landing forces.

Colonel General A. Gastilovich writes in his article that it is now scarcely feasible to conceive of a large naval landing force, since it is possible to destroy it with missile-nuclear weapons while they are still at their bases and at sea. Of course, if we expose our forces to the enemy, he will destroy not only the landing force but everything else as well. To prevent this from happening, the forces carry out measures of protection, defense, and forestalling the enemy in his operations. As in all other naval operations, modern methods of debarking landing forces take into consideration the possible employment of missile-nuclear weapons by the enemy.

Not very long ago our submarines, armed with ballistic (ballisticheskaya) missiles, participated in strikes by missile troops of strategic designation against deep enemy objectives. Now, with the appearance in our armament of intercontinental ballistic missiles which can reach any point on earth, missile submarines have been freed from these missions. It seems to us that such a step is premature.

It is known that our potential enemies are working on the interception of ballistic missiles. At the beginning of last year, the interception of an Honest John missile by a Hawk missile was demonstrated in the United States; now they are placing some reliance on the Nike-Zeus and Bloodhound missiles. One must believe that sooner or later everyone will learn to intercept ballistic missiles. Then, missiles launched from submarines will have advantages over intercontinental missiles because of their shorter range and lower trajectory. It will be more difficult to intercept submarine missiles,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and their floating launching position (plavayushchiy start) provides more favorable conditions than do fixed land launching installations (ustanovka).

The control of naval forces is now going through a crisis. This was particularly noticeable during the above-mentioned exercise in the Atlantic. The forces of two fleets participated in the exercise. The commanders took turns commanding them, not unlike the consuls of the early period of the Roman Republic. As the fleets move from north to south, the Commander of the Northern Fleet commands them as far as the 50th parallel. At this boundary he transfers the forces to his Baltic colleague, and then observes what is done with his vessels by the other commander. When the fleets move in the opposite direction, the change of commanders is repeated. Is it necessary to prove that this compulsory method is a half measure and that this is no way to command fleets? If, engaged in battle on the boundary of 50° North and, under the impact of a new situation, the forces changed the plans of operation of the large units as mentioned earlier, what confusion would ensue. Various vessels of the same large unit would report on their operations to various addresses and receive contradictory decisions from two staffs. Under these conditions it is also not quite clear which of the two commanders should bear the responsibility for the outcome of the entire operation.

The transfer of forces during the course of an operation, and at a great distance from shore at that, is intolerable. Zonal command is a remnant, a vestige of habit, left over from the territorial nature of the missions of the fleets in the recent past. Here is an attempt to combine new missions and new methods of combat operations, brought to life by new weapons, with the old forms of organization of the control organs of the forces. Earlier, when the missions of our fleets were tied to a limited territory and did not go outside the bounds of their naval theater, commanders of fleets were able to cope with the control of both the active operations at sea and the operations for the defense of bases and the seacoast. They also directed all of the types of combat and materiel-technical support. Now, when vessels of the fleet go out into the ocean, abandoning their bases for a long time, the commander is unable to control both without detriment, even if he is an absolute genius. The commander inevitable faces a gloomy prospect; he must either tear himself away from his theater and bury himself in the control of forces in the ocean far beyond the bounds of his theater, or transfer his ocean operations to a neighbor and command the defense of the theater himself.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The only possible way out of the complicated situation which has been created is through scrapping old forms of organization. In fact, such a scrapping has already been noted in places.

Each fleet assigned to operate in an ocean must have two independent commanders, subordinate to a center. One of these would be strictly the commander of the fleet, composed of submarines and long-range aviation. The other would be the commander of the naval district (morskoy voyennyy okrug), composed of all remaining forces. He would be responsible for the defense of the theater and all types of support of the operations of the ocean fleet.

Of course, the commander of the fleet must be a submariner, and his submarine command must bear the character of a field staff, capable of commanding forces at sea from a command post (KP) located wherever it is advisable according to the situation. In number of personnel, this staff would be half the size of the present staff of the submarine forces.

The proposed reform would not only remove our commanders of fleets from their dual positions but it would also increase the role of the commanders of submarine forces, who in point of fact only formally bear such a title at the present time, while in reality they play a passive role in the carrying out of operations and are removed from the command of their operational groupings (operativnoye obedineniye) at sea. In an alert, the commander of submarine forces usually abandons his command post and the forces subordinate to him and transfers to the fleet command post (FKP) of the commander of the fleet. There, he commands nothing. His lot is to be an assistant and help prepare correct decisions for the staff of the fleet.

It would be appropriate to note here that even the Main Naval Staff, on which there is not as yet one submariner admiral, is not free from that ailment.

The separation of the missions of the fleet into two groups, and the strict delineation of the functions of the two independent commanders and their staffs would finally unravel the knot of contradictions in the command of the forces, and introduce clarity into its organization. It goes without saying that in this case the need for the maintenance of a command of submarine forces disappears. The fleet commander alone, with his staff, would prepare and carry out operations at sea from start to finish.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

When the unified efforts of several fleets are needed, a unified command should be appointed.

Differing opinions give rise to several methods of command for submarines in the ocean. Debatable are the questions of the necessity of massing forces, the superiority of group operations over individual operations, the advantages of forcing submarine barriers with large units over the successive overcoming of the barriers without adhering to strict formations, and the delivering of strikes by large units in correct lines or by flexible waves (lava) free from formations.

When submarines did not have nuclear weapons, it was necessary to hit a battleship or aircraft carrier with eight to ten torpedoes to sink it. In order to achieve this, it was necessary to mass or group forces not only for delivering strikes against a large unit but even for destroying one vessel. The new weapons are capable of sinking a vessel of any class and displacement with one shot, and therefore it is no longer necessary to unite the efforts of several submarines to accomplish such a mission. However, this by no means excludes the massing of forces.

In spite of the opinion of Rear Admiral K. Stalbo (Morskoy Sbornik, No. 1, 1961), when delivering a strike, for example, against an aircraft carrier large unit, it is necessary to mass forces in order to attack it from various directions and disperse the attention of the defense forces of large vessels and their immediate protection. Massing is also necessary to insure uninterrupted (during short periods of time) delivery of strikes, from which the enemy will not succeed in rallying, and his damage and confusion from the first strike can be exploited by followup strikes. The firing of missile-nuclear weapons against vessels still must always be aimed.

Obviously, even when massing is necessary, atomic submarines must not be bound by line formations, correct close order, and geometrically measured combat arrays. All that is fine for games on maps. At sea, though, as experience shows, such formations can be maintained with difficulty only until the encounter with the enemy, after which the commander of the group (gruppa) or large unit loses control, and the complete independence of the submarine commanders ensues.

Even with the existence of ideal underwater communications, there is no need for atomic submarines to maintain squadron formations, no need for observance of the feeling of fellowship.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

New underwater speeds of submarines, and the range and accuracy of missile weapons, permit modern submarines to display more independence, initiative, and freedom of maneuver than before. Such ideal conditions, as in the past, such range (poligonnyy) support, as earlier, are not required now for successful attacks by them. The basis of the organization of atomic submarines must be waves (lava) or packs (stay), delivering massed strikes against a detected enemy large unit at an appointed time or a designated place.

The gathering of submarines in groups or large units during the stage of deployment, and outside of a battle or operation in general, does not give them any advantage in self-defense and only increases non-combat losses. Therefore, it cannot be justified.

Paths of development of forces. If mistakes in the determination of the main danger and most important missions of the Navy and miscalculations in the selection of the direction of the main strike and the main forces were not reflected in the determination of the paths of development of the Navy, then theoretical arguments of these matters would not go beyond the framework of academic discussions. However, basic mistakes in the orientation of the construction of vessels have already been permitted once in the Navy; so there is cause for sailors to argue, and they should be particularly thoughtful in approaching the selection of the paths of development of forces.

New technology and new weapons deservedly raise atomic submarines to the level of the main forces. With equal success, these submarines are capable of combating the main enemy nuclear weapons delivery vehicles (nositel) - the aircraft carrier attack large units - and of operating against the ocean communications lines and against objectives on the enemy coast. Therefore, it is understandable that primary attention has now been given to the construction of exactly this type of vessel . Considering that the existing danger from enemy missile-carrying submarines is no less serious than from aircraft carriers, the bearers of nuclear weapons, it seems to us that the same degree of attention should also be given to the construction of PLO submarines. However, that is not how matters stand here. Judging by information in the naval press (Sbornik statey zhurnala "Morskoy Sbornik", Special Issue, 1960, page 4), the construction of this only real means for combating atomic submarines carrying Polaris missiles is placed in the same rank with the construction of PVO vessels, landing vessels, and minesweepers.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Experience shows that in the construction of forces it is detrimental to be carried away by vessels of narrowly assigned purpose, such as, for example, submarine chasers or PVO vessels. The combining of a number of missions in one vessel noticeably reduces expenditures for construction. Therefore, it is necessary to strive for good designs (proyekt) of a universal submarine capable of accomplishing both attack missions and antisubmarine defense missions, a corvette with equally powerful PVO and PLO weapons.

The benefits that the combining of missions promises may be judged by the appearance in our armament of missiles suitable both for attacks against a coast and for firing against vessels. In the place of two designs of attack submarines, it is now possible to limit oneself to one.

The paths of development of the Navy and the degree of participation of its forces in a modern war will be determined not only by the decisive role of missile troops and the continental nature of the countries of the socialist camp, but also by the geographic position of the aggressor countries. Studying the composition and behavior of the members of the NATO military bloc, it is not hard to see that they are preparing aggression not only in Europe but also outside its borders.

In case of defeat, our enemies will evacuate their troops across the ocean, and, as was already pointed out above, the landing of our armies on other continents from the sea will be indispensable. It would seem that such a circumstance should have given rise long ago to the intensive construction of landing vessels. However, this did not occur, and in point of fact there are now no landing forces in the Navy.

The construction of landing equipment is facilitated by the fact that in peacetime landing vessels can be operated with success by all civil maritime and river departments, which can order the construction of these vessels in the quantities needed for defense. It is sufficient for the fleets to maintain one to two divisions (diviziya) for combat training.

It should be observed that the fleets prematurely denied themselves the services of the naval infantry, whose training for landing was undeservedly cast aside. The naval infantry were always the bearers of the heritage of naval landing operations, the arm of forces which was well trained in the art of those most crucial and dangerous

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

first assaults upon the shore. Even now, naval infantry has not yet lost its importance.

The experience of the work of naval organs of shipbuilding and armament shows that their predominately engineering management is weakened by the lack of managerial personnel with an operational backgrtound, knowing the nature of war. In the final analysis, the foundation of shipbuilding and armament lies, not in technology, but in tactics and operational skill. Therefore, to present to industry the correct and rigid requirements called for by modern war, it is necessary to have within the management of the organs of shipbuilding and armament, admirals who have personally experienced war in the past and understand well what is required for a war in the future.

APPRAISAL OF CONTENT : Documentary

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "Trends in the Development of the Tank Troops of the Soviet Army", written by General of the Army Aleksey S. Zhadov, First Deputy Commander in Chief of Ground Troops.

The article appeared in the 1961 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

Trends in the Development of the Tank Troops

of the Soviet Army

by

Army General A. Zhadov

Historically, Soviet military theoretical thought has responded actively and sharply to all problems of military science which have arisen with the appearance of new means of armed combat, technical equipment of armies, change in the organizational structure of the troops, and the methods of employing them in battle and operations.

Recently the pages of our journals on military theory and special research works have carried different opinions on the outlook for the further development of armor technology and on the organizational forms of tank groupings (obedineniye) and large units (soyedineniye) in the composition of the ground forces.

In this respect the article by Marshal of Armored Troops P. Rotmistrov, "Paths for the Further Development of the Tank Troops of the Soviet Army" (Special Collection of Articles of the Journal "Voyennaya Mysl", First Issue, 1961) merits attention. In this article a series of recommendations are made concerning the outlook for Soviet tank construction and the organization of the principal large units of the ground forces which have a definite practical interest.

At the same time it must be confessed that the formulation of several questions and the way in which they are elaborated are not convincing.

Marshal of Armored Troops Comrade Rotmistrov gives primary attention in his article to the conditions which determine the further development of tanks, the role of armor protection of tanks in connection with the development of antitank weapons, the significance of heavy tanks, and several questions dealing with the organization of tank troops.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

Let us examine these questions in the same order in which they have been formulated and give our point of view, without claiming to furnish a full exposition of the problems connected with the contemporary development of tanks and the organization of tank troops.

At the present time the basic trends in the development of anti-tank technology have been determined above all by the availability of missile-nuclear weapons and by the nature of a future war as a highly maneuverable one with the broad application of the means of mass destruction. Comrade Rotmistrov speaks about this point correctly in his article.

However, it is impossible to agree with his statement that "the tank troops, in close cooperation with missile troops and aviation, will be the deciding power in the ground forces". (p.26)

In our opinion, such a point of view is mistaken.

It is well known that large units of combined arms (tank and motorized rifle divisions), other arms of troops, and aviation will, as a rule, successfully carry out their tasks only if the results of missile-nuclear strikes are ably utilized. Specifically, during battles and engagements these strikes will be the main means of destroying the enemy. There is no need to prove the truth of this statement.

The role of tank troops in achieving the goals of a battle, an operation, and of the war as a whole will be great, but this role should be examined from the point of view of effectively utilizing the results of missile-nuclear strikes, for these in the final analysis constitute the principal force for the destruction of the enemy.

At the beginning of his article Comrade Rotmistrov correctly observes that the tank combines three basic combat characteristics: firepower, armor protection, and mobility. However, in the subsequent account, instead of examining all of these questions from the point of view of the nature of a future war, and determining the further paths for perfecting the combat characteristics of tanks, and above all of their armament, he first and foremost promotes the concept of heavy armor plating of tanks.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Tank armament. The tank is a combat vehicle and its existence is justified if it possesses powerful armament.

It is well known that during World War II (The Great Patriotic War) the maneuverability of our medium and heavy tanks was significantly superior to the German "Tiger" and "Panther" tanks, but until the middle of 1943 they were inferior in armament. These tanks, which had guns of 75-88 mm., higher muzzle velocity, and greater grazing range, caused great damage to our tanks. However, when our tanks and assault guns (SU) received guns of 85-152 mm. this superiority was practically eliminated.

In the postwar period, with respect to the perfection of tank armament, we have paid more attention to raising the accuracy of fire in motion, armor-piercing capability, and the feasibility of delivering fire at night even under conditions of poor visibility. However, the artillery systems with which our tanks are now armed are not much more powerful than those on our tanks at the end of World War II.

It is true that we have recently developed artillery systems with a muzzle velocity for armor-piercing shells on the order of 1,000 m/sec and greater for rifled guns, and 1,600 m/sec for smoothbore guns. But even these artillery systems, provided for the armament of medium tanks, are only transitional.

An analysis of combat operations and some experience shows that a modern tank should be armed with the most modern (perspektivnoye) missile weapons, which will enable effective destruction at a great distance of any enemy tanks, either moving or stationary. Under contemporary conditions on the field of battle there will also be many other targets, such as self-propelled artillery, protected by armor, armored carriers, armored prime movers, and various targets with light cover which must be annihilated from great distances without expending heavy-caliber artillery shells or missiles in the process. For the destruction of these targets, tanks should have, besides guns or missile systems, other powerful armament, such as heavy-caliber machine guns or small-caliber guns, since the machine guns now on tanks do not enable the destruction of varied and numerous lightly armored and other targets at a distance of 1,500-2,000 m. and more.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

The antiatomic protection of tanks. Together with powerful armament, modern tanks should afford dependable biological protection of the crew from the contaminating elements of nuclear weapons, and mainly from penetrating radiation. Solving this problem only by increasing the thickness of the armor has not proven feasible. The steel armor should guarantee the necessary strength of the hull of the tank against the effects of the blast wave. Dependable biological protection of the crew may be achieved by using a special "lining", which will stop the stream of neutrons, or by building special structures inside the tank into which the crew must be put. The latter require structural changes in the tank, the reduction of the crew to 2-3 men, and the automatization of all processes of the conduct of fire, driving, and communications. The necessary work in this direction is already being carried out.

The armor protection of tanks. In discussing the role of armor protection of tanks, the author strongly attacks those who promote the idea of increasing the maneuverability and transportability of ground forces large units by decreasing the weight and overall dimensions of tracked and other combat vehicles.

Nor do we propose increasing the maneuverability of ground forces large units and units (chast) by sharply weakening the armor protection of tanks and other combat vehicles.

However, in deciding this question there cannot be yet another extreme, which, as a matter of fact, Comrade Rotmistrov advances, defending the necessity of retaining heavy tanks having thick armor.

Ever since tanks became a massive weapon on the field of battle, they inevitably called for the creation of new means of combating them. The competition of armor with projectiles has continued over a period of forty years. In this single combat between armor and antitank fire, as of today the latter has retained the advantage.

Incidentally, this is conceded even in the works of the Academy of Armored Troops which have appeared under the editorship of Marshal of the Armored Troops Comrade Rotmistrov. Thus, in the Collection of the Works of the Academy No. 177, which appeared last year, it is candidly pointed out that the armor protection of tanks lags behind the development of the means of its destruction, and in connection with the appearance of antitank guided missiles, this lag

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

has become even greater.

Defending the concept of powerfully armored tanks, Comrade Rotmistrov casts doubt upon the effectiveness of modern antitank guided missiles (upravlyayemyy reaktivnyy snaryad - PTURS). Presenting the tactical-technical data of these missiles, which our potential enemies have, he categorically asserts "that their appearance in the family of weapons of mass destruction and tanks does not for the present afford sufficient basis for concluding that it is inexpedient to provide our basic types of tanks with powerful armor protection". (p. 30.)

It is well known that every weapon has its positive and negative sides. For the present even antitank guided missiles have their negative side. However, in appraising these means of combat, Comrade Rotmistrov emphasizes primarily their deficiencies. But this does not detract from the effectiveness of antitank missiles and the broad prospects for their development. They are becoming more and more universal and can be used not only for all types of ground combat vehicles, including tanks, but even against helicopters. It is inconceivable not to reckon with this possibility.

The development of the PTURS, of course, does not mean that tanks have been repudiated. This merely presents us with the problem of searching out new ways of defending tanks from antitank weapons.

It is well known that the KV heavy tank was developed by us before World War II for breaching fortified areas, defense zones, and also for combat with enemy tanks. But in the course of the war our troops usually bypassed fortified areas. Therefore, heavy tanks were used as a means of close support of infantry in breaching strong position defenses, and especially for combat with enemy tanks. As a result of the large amount of metal consumption, the high cost, and their insufficient maneuverability, a very limited number of these tanks were produced during the war. Instead of heavy tanks for combat with assault guns (shturmovoye orudiye) and tanks of the enemy, we began to produce a large number of assault guns (SAU) on the chassis of medium and heavy tanks.

Therefore, our self-propelled and ordinary artillery, and also our heavy tanks, bore the main brunt of combat with enemy "Tiger" tanks and "Ferdinand" assault guns. By virtue of the great weight

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

and slight mobility of these enemy vehicles on the field of battle, and in spite of their heavy armor, they were successfully shot up even by our medium tanks armed with 85 mm. guns.

Under modern conditions the problem of breaching enemy defenses will be solved mainly by atomic weapons. And, in general, the type of defense in place used in the last war will rarely occur.

It may now be asked, is there a need for heavy tanks to solve the problem of breaching defenses? Of course not.

Knowing this, Marshal of Armored Troops Comrade Rotmistrov tries to analyze heavy tanks as a means of qualitatively strengthening medium tanks, reckoning that the latter are inferior in power and armor protection to the medium tanks of our probable adversaries. For this purpose, the American medium tank M-60, the basic tank of the U. S. Army, is compared with our T-55 tank. But the parameters used in this comparison do not give a correct conception of the combat qualities of these vehicles. Nor is it easy to compare an American tank with our T-10M, insofar as the latter is considered a means of qualitative reinforcement of our T-55 tank.

In the case in point, comparisons are made of parameters such as armor protection, unit of fire, engine horsepower, fuel capacity, caliber of gun, and muzzle velocity. For example, the horsepower of the T-55 engine is 580, while the M-60 has a 750 hp engine. However, taking into consideration the relative weights of the two vehicles, the unit power ratings are identical. The fuel capacity of the American tank is twice as great as ours, but the rated cruising range of both tanks is practically identical. As far as the armor protection of our medium tank is concerned, the armor on the turret is significantly thicker than that of the M-60, while the armor protection of the hulls is almost the same.

Despite the somewhat greater caliber and muzzle velocity of the armor-piercing shell of the American tank, in comparison with the armor-piercing shell of the gun on our medium tank it does not enjoy any particular advantage with respect to effectiveness.

In comparing our T-10M heavy tank with the M-60, we see that the armor protection of their hulls is the same, with the exception of the armor on the turrets, where our tank has much thicker armor. In terms of armament, the muzzle velocity of the armor-piercing shells of both

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

tanks is identical, and differ only in their caliber. But the presence in the unit of fire of the American tank of a subcaliber projectile (and possibly a shaped-charge shell too) renders it a sufficiently strong weapon for combating our heavy tank. The cruising range of the M-60 is almost twice that of our tank. Both tanks have power plants of identical unit power rating. Consequently, their mobility on the field of battle in moderately rugged terrain is about equal.

As is evident, it is hardly proper to speak of specific advantages of our T-10M heavy tank over the American medium and heavy tanks.

The necessity for having heavy tanks is also based on the fact that the Americans have at their disposal different systems of artillery of 150-240 mm. on tracked chassis, which is a means of reinforcing their medium tanks. Combat with this artillery is supposed to be waged by heavy tanks with the thickest armor protection, as though our medium tanks were not capable of carrying out this combat over great distances. Such claims have hardly any basis.

It seems to us that in order to achieve superiority over the enemy we do not require the production of heavy tanks, which are three times more expensive than the medium tanks and only slightly superior, but rather a sharp improvement of the combat qualities of our medium tanks, primarily the power of their armament.

As we pointed out above, this problem in tank construction has basically been solved successfully already. We now have a medium tank which is not inferior to, and even surpasses, the modern heavy tank in terms of armament, armor protection, and protection against the contaminating elements of nuclear blasts. Moreover, it has a higher rated cruising range and greater maneuverability. New models of such tanks will be armed with artillery systems with a muzzle velocity for armor-piercing projectiles of 1,015 - 1,600 m/sec, which will be capable of piercing the front armor on the American M-60 tank at a range of more than 1,000 m, and the side armor at a distance of 3,000 m.

These tanks are not only not inferior to, but significantly outclass, all known models of foreign tanks with respect to the parameters of rated cruising range, maneuverability, armor protection, and weight.

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Therefore, there is no reason to fear that the repudiation of heavy tanks may entail the loss of our present qualitative superiority over enemy tanks.

But this certainly does not mean that we should immediately remove our modern heavy tanks from the arsenal and have them melted down. In case war should break out, they can be used successfully for filfilling many combat tasks.

Having called for a scientific approach to the solution of the question of heavy tanks, as we have seen, Comrade Rotmistrov does not propose anything new in the field of tank construction to correspond with the requirements of a possible war, but merely defends the old trend in the development of tanks, leaning solely on the experience of World War II.

Considering exclusively the mobile nature of a future war, the increased role of airborne troops, and the necessity of transferring motorized rifle divisions by air over significant distances for fulfilling combat missions which may arise in the course of an operation, we will require, besides a basic type of medium tank, a light tank with powerful conventional and missile armament.

Our present light tank, the PT-76, has for the present only one quality - it is amphibious. But this tank has such weak armament and large dimensions that it cannot be transported by air. Therefore our efforts should be directed toward designing a light tank which would be powerfully armed and whose weight and dimensions would allow it to be transported by air. At the same time, such a tank should possess tactical mobility which would enable it to cross water barriers afloat, and high speed on the field of battle. Such a tank is highly necessary both for fulfilling reconnaissance tasks and for other types of combat support.

Under modern conditions, a high and reliable degree of destruction of the enemy with missile-nuclear weapons will often permit an attack to be carried out without the infantry having to dismount. This circumstance means that we must have a highly maneuverable armored carrier with a powerful antitank missile weapon and a small-caliber gun or large-caliber machine gun. The design of such an armored carrier should have the necessary antiatomic resistance and should assure biological protection of the personnel inside. Its dimensions should afford the simultaneous transportation of a 10-12 man rifle squad. In connection with this, it is advisable at the

[redacted] 1.3(a)(4

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

present time to have a rifle platoon consisting of two squads so that its organizational structure will not be disrupted in movement by armored carriers. It should be emphasized that even in peacetime such a squad would be more spunky and lively.

Marshal of Armored Troops Comrade Rotmistrov very sharply criticizes those comrades who propose new organizational forms of the basic large units of the ground forces. In particular, those comrades who propose the creation of a unified organization of the basic large units of the ground forces are just about viewed as dangerous people who have encroached on such concepts as "tank troops", "tank formations" (gruppirovka), tank armies, and tank divisions. It seems to us that it is incorrect to speak from such positions about people who propose new forms of organization of our troops. Life itself raises problems of perfecting the organization of the troops.

Alluding to the experience of the Second World War, Comrade Rotmistrov declares "that not rifle divisions, reinforced by tanks, decided the success of an operation, as French military theorists thought, but rather tank divisions, tank corps, and tank armies" (p. 34).

It must be stated that Soviet military theorists and practitioners have never propounded the role of tank and combined arms large units during the past war in such a way.

Everyone knows that during the Second World War the success of offensive and defensive operations was decided by precise coordination of rifle large units and groupings, reinforced by artillery and tanks, with tank corps and armies, along with the massive utilization and support of artillery and aviation, and also the constant support of operations by special branches of troops and by the rear area.

Incidentally, neither the Germans nor the Americans, and the French even less so, ever succeeded in achieving such harmonious coordination. On the whole, German reliance on tank troops and aviation proved to be unsound.

Unfortunately Comrade Rotmistrov's discussions of the experience gained in World War II neglect this side of the question. Ascribing an exclusive role to the tank troops, he introduces as an example the meeting engagement at Prokhorovka on 12 July 1943.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In his opinion, during this engagement the strikes of the German tank forces were countered only by our tank troops, and specifically by the Fifth Guards Tank Army under the command of Comrade Rotmistrov. The Fifth Guards Army, as he writes, not only did not follow the order of the commander of the Voronezh Front on the joint delivery of a counterthrust, but did not withstand the enemy onslaught, and left the line being held.

It is impossible to agree with such an appraisal of the events. For the delivery of a powerful counterthrust at Prokhorovka, General Headquarters (Stavka) had reinforced the Voronezh Front significantly at the expense of the strategic reserves. In this counterthrust there participated powerful forces of all branches of the troops composing this front, and by their joint efforts (and not merely by the Fifth Guards Tank Army) halted and then threw back to their original position the tank corps of the enemy. We render due credit to the performance of the Fifth Guards Tank Army, which played an important role in delivering the counterthrust. But other armies of the front also played an important role in the execution of this action. To ignore this fact will lead to excessive exaggeration of the role of the tank troops and, in particular, of the Fifth Guards Tank Army.

It is well known that the forces on the Voronezh Front were not able to develop a counterthrust on 12 July because of the extremely complicated situation on the southern face of the Kursk Arc. And in this respect, the task posed to the troop commanders of the front was not fulfilled. Among those who did not fulfill their mission of 12 July was the Fifth Guards Tank Army. Therefore, a one-sided accusation of only the Fifth Guards Army for non-fulfillment of the order sounds clearly unconvincing and unobjective.

As far as the performance of the left flank corps of the Fifth Guards Army is concerned, which Comrade Rotmistrov writes about, it must be stated that on 12 July large units of this corps repelled the blows of superior enemy forces from the line being held. Only towards evening did the enemy succeed, by employing its superiority in tanks, in forcing back one division of the corps a fairly short distance.

In his article Comrade Rotmistrov time and again emphasized the necessity for a scientific approach to the utilization of the experience gained in the last war. At the same time, in disucssing the

[redacted] 1.3(a)(4

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

events at Prokhorovka, he definitely digresses from this criterion and attempts to compare incomparable quantitites. It is well known that the Fifth Guards Army in the engagement at Prokhorovka did not have tanks and that this substantially limited their combat capability in a battle with a strong tank formation of the enemy. Quite different was the situation of the Fifth Guards Tank Army, which had (together with the attached tank corps) around 850 tanks and assault guns. In evaluating the role of tank corps and armies in operations during the last war, it is impossible to compare mechanically their combat capability with the combat capabilities of rifle divisions, corps, and combined arms armies. Every comparison which lays claim to being scientific should be based on a deep analysis of these and other large units and groupings of troops.

It is generally necessary to state that it is impossible to take isolated examples from the experience of combat operations of the troops during World War II and on the basis of these to draw conclusions about the organization as of the present and the possibilities of basic large units and groupings of the ground forces.

It is quite clear that the most serious and dangerous error which can be committed in using examples from military history for the development of military theory is to attempt to transfer mechanically the experience of the past to the present. In spite of his great experience in military-theoretical research, it seems to us that Comrade Rotmistrov has committed just such an error.

Modern trends in the development of the ground forces consist of continuously equipping them with new technical means of combat. In this respect the relative preponderance of tanks is growing particularly fast. Under these conditions there can be no question of diminishing the role of the tank troops. We can merely consider their most purposeful organizational development.

At the present time we have two types of divisions - motorized rifle and tank - and these afford the requisite maneuverability and the introduction of vigorous and decisive actions into battles and operations. Tank divisions possess great penetrating power which increases their independence in conducting combat operations. They are more mobile and maneuverable and have very high cross-country ability off roads, better resistance against nuclear weapons, and less cumbersome organization than motorized rifle divisions.

[redacted]

1.3(a)(

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

However, the experience of many exercises shows that the presence of heavy tank regiments in these divisions reduces their operational maneuverability and complicates the supply problem in the course of battle. Therefore, army tank commanders have made what we belive to be correct proposals on replacing these regiments with medium tank regiments. Heavy tanks would then be placed most purposefully in heavy tank divisions or in separate tank regiments.

Our motorized rifle divisions have fewer tanks than tank divisions, but are superior to them in artillery, and particularly in antitank weapons. Therefore a question arises regarding further perfecting of the organizational forms of both divisions in order to achieve a successful combination of the positive qualities in both.

Nor is it possible to agree with Comrade Rotmistrov concerning the advisability of creating a light motorized rifle division. Judging by the type of missions which are assigned it, and also by its technical equipment, such a division would not differ particularly from the present airborne division.

And now several words about our armies. We do not know who has raised the question of abolishing our present tank armies, as Comrade Rotmistrov conjectures. At the same time, an analysis of the combat capabilities of modern armies and the experience derived from large command staff and army exercises show that a combined-arms army with a composition of two tank and three or four motorized rifle divisions with appropriate missile and special weapons (considering that this army operates in the direction of the main efforts of a front) is not inferior in the number of tanks to a tank army composed of four divisions, and in other factors will be significantly stronger.

A tank army has great penetrating power and great mobility and maneuverability, particularly in operations in areas with a limited number of roads. But under modern conditions the development of an attack at a high tempo creates an extremely difficult situation with respect to the deployment and introduction into an engagement of a tank army. Often a tank army cannot break away from a combined arms army, which also has tremendous mobility. Moreover, the enemy, knowing of the presence of a tank army in a front, searches it out, and having detected it will attempt to destroy or weaken the army principally by strikes of missile-nuclear weapons. This is why we should seriously study the organization and means of combat employment of modern armies in operations. Owing to these and other circumstances,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

we should study profoundly the organizational forms of modern armies.

It is incomprehensible why Comrade Rotmistrov places the necessity for the existence of the tank division, when no one doubts this, in direct dependence on the existence of the tank army. These are two different questions and should not be confused.

There is no doubt that in the last war tank armies and tank corps basically played a fundamental role in the development of operations at high tempos. Under modern conditions high tempos of development of operations will depend mainly on the skillful utilization of nuclear weapons and missile troops. In this respect, not only tank, but also combined-arms armies, must develop high rates of advance. In a number of cases, the latter will have more, not less, tanks than tank armies of four divisions.

In meeting engagements, principally nuclear weapons will play the major role. The success of operations by tank and motorized rifle large units will depend on the skillful utilization of these weapons. Therefore, there is no need to speak of some special exception of tank large units and groupings.

Life goes forward, and our armies are being equipped more and more with the latest means of armed conflict, which requires corresponding organizational development, and we should welcome all generals and officers who work at the solution of this complicated and serious problem.

SOURCE: Reliable Soviet source (B) who has access to this type of document.

. . . Following is a verbatim translation of an article entitled "The Use of Naval Forces in Closed Sea Theaters in the Initial Period of a War", written by Admiral Vladimir A. Kasatonov, now Commander of the Black Sea Fleet and formerly Commander of the Baltic Fleet.

The article appeared in the 1960 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. The month of publication of the 1960 Second Edition is unknown. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

The Use of Naval Forces in Closed Sea Theaters

in the

Initial Period of War

by

Admiral V. Kasatonov

The qualitative leap in the development of the means of armed combat on the sea, which has occurred in an unprecedentedly short period of time, has placed before the art of naval warfare a series of problems connected with the development of methods of operations ensuring the fullest realization of the potentialities of new weapons for effective accomplishment of the missions of the fleets.

In recent years a considerable amount of work has been done in the Navy both in the field of construction and the development of forces and in training for the conduct of combat operations under new conditions. At the present time, the development of new weapons and the tempo of equipping the Navy with them has reached a level which urgently demands that the main attention be given to methods of using these weapons. It is becoming entirely obvious that even at the current stage the most important missions will be accomplished by strike forces of the Navy with missile and nuclear armament. We have in mind, first of all, submarines armed with cruise (krylataya) and ballistic missiles or long-range torpedoes with nuclear warheads, missile aviation, (raketnaya aviatsiya), coastal missile units, and, to a certain extent, missile surface ships and boats (kater), capable even under current conditions of accomplishing a number of combat missions in sea theaters.

The high combat qualities of the strike forces create new potentialities for the Navy as a whole, make it possible to accomplish missions in a new way, and set up goals which were impossible to achieve not long ago. It is necessary to consider

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the employment of these forces under concrete military-geographic conditions of this or that theater of military operations. It is well known that the missions and methods for accomplishing them will be considerably different for the fleets in open sea theaters, such as the Northern and Pacific Fleets, and for the fleets in closed sea theaters such as the Black Sea and Baltic Fleets. However, it must be kept in mind that at present the conception of "the closed sea theater" does not reflect completely accurately the nature of the conditions for operations of the forces of the fleet in it. The point is that the activity of the fleets in the closed sea theaters is not at all limited by the closed seas such as the Black Sea and the Baltic Sea, as it was several years ago, but must be carried out to a large extent beyond the limits of these seas to accomplish the most important missions. The characteristics of the new weapons make it possible for the fleets to carry out such missions. However, for this it is necessary that part of the forces afloat, above all, submarines, be deployed beyond the limits of the closed seas even before the beginning of military operations, and that these forces be built up during the course of a war through movements from other sea theaters or after the seizure of straits zones by the ground forces. The operation of aviation beyond the limits of the closed seas is linked with the necessity, while flying over enemy territory, of overcoming the powerful countermeasures of the PVO system which has evolved. These circumstances constitute one of the most important features of closed sea theaters.

Characteristic of closed sea theaters is the presence of three large zones in which the conditions of conducting combat operations are substantially different. To such zones belong: the closed sea (for example, the Black Sea and the Baltic Sea), the zone of the straits with the adjacent narrows and islands, and the more open and extensive sea (for example, the Mediterranean Sea or the North Sea).

Among the most important missions of the Navy in closed sea theaters in the initial period of a war, it is possible to name two fundamental missions. One of these is the defense of one's own seacoast and the adjacent territory against attacks from the sea. The main element of this mission is

[redacted]

1.3(a)(4)

combating enemy aircraft carrier large units (soyedineniye) operating in a given operational direction, with the goal of warding off the nuclear strikes of the aircraft carrier aviation forces against the coastal and immediate rear area economic and administrative-political objectives of the country, the forces of the Navy, and the maritime fronts. Thus, in substance, this mission is similar to an analogous mission accomplished by fleets in open sea theaters. However, in the conditions of operations of forces and the methods of their accomplishment, the mission in closed sea theaters has substantial peculiarities, as we shall show below.

The second fundamental mission is support (sodeystviye) of the ground forces in attack and defense, including support in the operation for seizing the straits zones, with the subsequent exit of submarine forces through the straits for operations in more open areas of the sea theater. To accomplish this mission it is also necessary to combat aircraft carrier and missile vessel (raketonosnoye) large units and prevent the entry of naval forces of the enemy through the straits into the closed sea, or disrupt their combat activity in the straits zone and in the area just outside the straits.

On behalf of a maritime front it may be necessary to accomplish other missions, such as support of the ground forces in forcing the straits and in seizing islands of the straits zone, disruption of the sea transport of the enemy, protecting one's own transport, etc. Furthermore, under current conditions it is possible to examine anew the problem of fire support for the maritime flank of the ground forces. Now, of course, there can be no talk of the delivery of fire strikes against the flank of enemy ground forces by tube artillery of surface vessels. At the present time, such a mission is clearly unrealistic. The problem is the employment of the missile forces of the Navy for delivering strikes against enemy ground forces from distances of several hundred kilometers with nuclear warheads. In spite of the fact that the activity of the Navy must be directed, first of all, toward combat with the naval forces of the enemy, on a number of occasions, when it is required by the situation on land and permitted by the situation at sea, it is advisable

to bring in missile forces of the Navy, mainly submarines and coastal missile units, to deliver nuclear strikes against objectives on land for the benefit of the troops of a front. However these operations may not be conducted to the detriment of the accomplishment by the Navy of its basic tasks at sea.

A few words about the operations of the Navy on the sea communications lines of the enemy. In our opinion, during the first days of the initial period of a war in closed sea theaters, this mission will not have important independent significance, since during that period the main forces of the Navy must be directed toward the fastest possible destruction of the strike forces of the enemy fleet - the bearers of nuclear weapons. The mission of disrupting military sea supply during the first days of a war must be accomplished only to the extent necessary as one of the special missions for support of the ground forces. During the subsequent period, the importance of this mission may increase sharply in conjunction with the fact that after delivery of the first missile (airborne missile - vozdushno-raketnyy - on the part of our enemies) strikes, replenishment and regrouping of forces will be required for the development of further military operations. It should be expected that by this time a convoy service in sea theaters of military operations will have been organized by both sides. The most favorable conditions for combat against the sea communications lines will be created after the seizure of the straits zones by our troops, the exit of submarine forces out through the straits into the more extensive areas of the sea theater, and the organization of basing for units of the strike forces and the bulk of the support forces for seized enemy bases.

To determine correctly what forces of the Navy are needed in closed sea theaters for successful accomplishment of the missions enumerated above, one must consider the fact that the accomplishment of each of the missions is linked with definite geographic areas to a considerably greater degree than in open sea theaters. Thus, the mission of destroying the aircraft carrier attack large unit (AUS) must be accomplished beyond the limits of the closed sea, since the possibility of aircraft carriers entering into that part of the sea theater is practically out of the question. Operations for disruption of the entry of the forces of the enemy fleet through the straits and disruption of their combat activity in the straits zone must also be accomplished beyond the

limits of the closed sea. In a number of instances this will require the concentration of main efforts in the straits zone itself. At the same time the mission of fire support for the maritime flank of the ground forces and a number of other missions for support of a front will be accomplished during the first days of war within the limits of the closed sea. Thus, in closed theaters it is necessary to have strike and support forces with a composition capable of accomplishing missions in all three basic zones of the sea theater.

Of all the arms of forces of the Navy, only submarines and aviation are capable of carrying out combat operations in the open part of a theater at the present time.

The main mission of these forces must be the destruction of enemy naval vessels already at sea; it is advisable to entrust the destruction of enemy naval vessels at their bases to the missile troops of the Supreme High Command (VGK), which can accomplish such missions more effectively.

Speaking of the use of submarines, it should be pointed out that their penetration into the above-mentioned areas of a sea theater, their conduct of combat operations there, and also their materiel and technical support (replenishment of ammunition, fuel, and relief of personnel) is linked with the necessity of overcoming the anti-submarine defense developed by the enemy. At the same time, having penetrated into the area of combat operations, the submarine must carry out combat operations for as long a period of time as possible with maximum effectiveness. This requirement is met to the greatest degree by fast submarines with atomic engines, armed with long-range torpedoes with nuclear warheads (with the condition that the depth of the sea permits atomic submarines to run at maximum diving depth as, for example, in the Mediterranean Sea).

Being able to stay at sea for a practically unlimited period of time, atomic submarines can be in waiting areas sufficiently remote from the zones most densely saturated by the forces and facilities of anti-submarine defense (PLO), execute a swift movement to deliver nuclear strikes against detected enemy naval vessels, and subsequently break away from pursuit by the anti-submarine forces. Beyond the limits of a closed sea it is also advisable to use missile submarines (with the condition that they use cruise - krylataya - missiles with homing - samonavedeniye). However, for this, the execution of special measures for the

organization of accurate target designation and subsequent replenishment of expended missiles will be required.

Besides the destruction of naval vessels, special submarines must carry out reconnaissance of enemy naval vessel large units and convoys for the delivery of strikes against them by the forces of missile aviation and attack submarines. They must also combat enemy submarines, including missile-carrying submarines, the possible use of which is highly probable even in the immediate future.

To accomplish the missions of destroying highly maneuverable enemy formations in relatively extensive areas of a sea theater, it is necessary to have at the disposal of the fleet missile aviation capable of delivering strikes against enemy naval vessels with cruise missiles, both independently and in coordination with submarines, at a distance of up to 3,000-4,000 kilometers from their airfields. To carry out aerial reconnaissance for these forces, there must be long-range reconnaissance planes in the composition of the reconnaissance aviation of the Navy.

A quite unique area for carrying out combat operations is the straits zone, within which the operation of submarines and surface vessels is practically out of the question, and the operation of missile aviation is hampered by the small dimensions and intricate configurations of the reaches and straits among the islands. In view of the large number of islands, the detection of enemy vessels in the straits zone by any means of technical surveillance is considerably hampered. Not long ago the only arm of forces of the Navy capable of carrying out combat operations in such areas was mine - torpedo and fighter aviation. Such operations were unavoidably coupled with large losses, since straits zones are saturated to the greatest degree by the forces and facilities of antiaircraft defense.

The situation changed with the introduction of nuclear-missile weapons into the armament of the Navy. For strikes against points of basing and clusters of vessels detected in anchorages, missiles from submarines and the launching installations of coastal missile units of the Navy can be used, independently and in coordination with units and large units of the operational (operativnaya) missiles of the ground forces. The submarines can deliver strikes from firing positions located in a closed sea at distances of 400 to 500 kilometers, and the coastal missile units, from firing

[redacted] 1.3(a)(4)

positions on the seacoast.

Nuclear-missile means of destruction can also destroy formations of vessels during their passage of the straits. Since narrow straits are accurately determined zones, it is possible to use missiles effectively against areas calculated in advance in any sector of a strait. Using nuclear warheads of suitable force, it is possible to achieve the required destruction of an enemy formation forcing the straits with a limited number of missiles. At the same time one should take into account that for the destruction of small groups or individual small vessels in a heavily interrupted area of a sea theater, and also for the destruction of small targets at sea and on the coast, the use of nuclear-missile weapons will, in a number of cases, prove to be inadvisable. Therefore, supporting the opinion of a number of authors (for example, Colonel General A. Gastilovich[1] in the first [1960] issue of Spetsial'nyy sbornik statey zhurnala "Voyennaya Mysl") that the fighter-bomber should be considered the basic aircraft of front aviation, we are convinced that just such a plane is also essential to the Navy for combating vessels and aviation of the antisubmarine defense in the interests of the support of the combat operations of submarines, the destruction of the facilities of coastal technical surveillance, and the execution of other missions.

In the immediate future coastal missile units must become the main strike force of the fleets in combating enemy naval vessels within the limits of the closed sea (and partially even in the straits zone). These units, armed with cruise missiles with a range of more than 500 kilometers, with inertial guidance (avtonomnoye upravleniye) for firing against areas, and with a homing device (ustroystvo samonavedeniya) for destruction of vessels at sea, will be able to cover with their fire the entire waters (akvatoriya) of a closed sea and make enemy combat activity and the operation of enemy naval vessels and transports within its limits practically out of the question. The limited dimensions of closed seas make it possible to use to the fullest extent modern radio navigation and hydroacoustic navigation systems of high accuracy to provide orientational support to reconnaissance vessels and planes, which in turn makes it possible to provide accurate target designation for coastal

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

missile units. Target designation can also be effectively provided by long-range coastal radar stations.

However, the high combat potentialities of coastal missile units do not eliminate the need for a small formation of missile submarines in the composition of a fleet operating in a closed sea theater. These submarines are needed both for delivering strikes against enemy vessels and objectives in the straits zone and for the fire support of the maritime flank of the ground forces. In the near future submarines will be armed with cruise missiles with a homing device for the final portion of their trajectory and will also be able to be used for the destruction of vessels at sea, particularly after these (missile submarines) have exited through the straits into the open part of a sea theater.

Taking these considerations into account, it is advisable to have in the composition of a fleet in a closed sea theater, submarines armed, not with ballistic missiles, but with cruise missiles, assuring the possibility of multipurpose use of the same submarines. To the credit of cruise missiles there is one more circumstance of no small importance, that with their launch from submarines the enemy does not have the opportunity of getting a fix on the missiles in flight to determine the trajectory and the point of launch, and consequently, the location of the submarine. With the use of ballistic missiles such a task is accomplished fairly easily under modern conditions, particularly within the limits of a closed sea with small dimensions. Having determined the location of a missile submarine, the enemy would be able to direct his antisubmarine forces in pursuit of her.

In addition to missile submarines, it is necessary to have in the composition of the fleet a numerically larger formation of torpedo submarines designated for the destruction of enemy vessels and transports at sea, carrying out reconnaissance at the exits of the straits and bases, and accomplishing a number of other missions. One of the most important missions of the torpedo submarines will be the prevention of secret infiltration of enemy submarines through the straits into a closed sea, and the destruction of submarines detected within the limits of this sea.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Finally, surface missile vessels (particularly missile boats) must occupy a definite place in the composition of the strike forces of the Navy in closed sea theaters. In our view, the main mission of surface missile vessels will be combating surface vessels of the antisubmarine defense, carrying out combat operations against the sea communications lines of the enemy in order to protect our own sea supply, and also combating enemy vessel forces in the island areas while supporting the ground forces in seizing the straits zone and in support of the exiting of submarines through the straits.

The combat durability of surface missile vessels can be increased primarily by providing them with reliable antiaircraft defense, especially by arming these vessels with antiaircraft missiles and including special PVO vessels in the battle order of missile formations. The conditions of closed theaters make it possible to provide PVO for surface vessels to a considerable extent by use of the forces and facilities of the maritime large units of the troops of the PVO of the Country.

Side by side with its strike forces, a fleet must have in its composition perfected forces of antisubmarine defense: antisubmarine vessels, antisubmarine aviation, fixed antisubmarine facilities, and also forces and facilities of antimine defense, the basis of which are minesweepers. To provide timely data on low-flying aerial targets to the strike forces of a fleet and the troops of the PVO of the Country, it is necessary to have in the composition of a fleet radar patrol submarines and surface vessels. Because of the aim of our enemies to use low altitudes to the maximum degree for the flights of their aviation, it is impossible under current conditions to ensure timely and effective use of the forces and facilities of the PVO to repel an air attack without a sufficient number of these vessels.

The conduct of aerial reconnaissance in closed sea theaters is highly complicated because of the necessity of carrying out flights over enemy territory having a powerful antiaircraft defense system organized in advance. Therefore, the presence in a fleet of a sufficient number of modern reconnaissance aircraft for carrying out short-range and long-range reconnaissance is a primary necessity.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Finally, the fleet must have at its disposal potentialities for accomplishing yet another of its missions. We are talking about tactical naval landing operations (desant). In the course of the execution of operations by the ground forces for the purpose of seizing straits zones and also individual islands and groups of islands, it may be necessary for a fleet to debark small tactical landing forces in coordination with airborne and tank landing forces (desant). A fleet may also be given the mission of supporting troops of a front in forcing the straits, using its means to carry out the ferrying of units of troops and combat materiel.

To fulfill these missions, a fleet will require from the initiation of military operations a certain amount of fast and small amphibious transport means. To avoid wasteful expenditures on the composition of these means in peacetime, it is advisable to have them under the authority of civil maritime organizations, rather than in a fleet, and to use them in the national economy for internal sea and river transport. The experience of operating landing craft left over from World War II proved that they are a suitable and economic means for short hauls, particularly when loading and unloading cargo on a seacoast not equipped with wharves.

Thus, the nature of the missions of the fleets and the military-geographic conditions of the closed sea theaters require, in general, the following forces within the composition of these fleets:

- submarines: missile, with cruise missiles; torpedo, with nuclear and conventional torpedoes of different designation; and also radar and hydroacoustic patrol submarines;

- aviation: missile, reconnaissance, and antisubmarine;

- coastal missile units, armed with cruise missiles with an inertial (avtonomnaya) guidance system and homing;

- surface vessels (and boats): missile, antisubmarine, PVO, landing (only in wartime), radar patrol, and other special vessels.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It is quite obvious that for the support of the basic forces enumerated it is necessary to have an auxiliary fleet corresponding in size and purpose, including submarine tenders, supply ships, emergency rescue ships, repair ships, etc.

Now let us examine some problems pertaining to the accomplishment of typical naval missions, using the forces and weapons mentioned.

Destruction of aircraft carrier attack large units. The mission of destroying aircraft carrier attack large units in closed sea theaters is no less real than in open sea theaters. For example, in the Mediterranean Sea, constantly being redeployed and maintained in high combat readiness, is a big aircraft carrier large unit, the U.S. Sixth Fleet, having in its composition two heavy aircraft carriers, cruisers, and destroyers. The Sixth Fleet is the main strike formation of the naval forces of NATO in the southern direction which is actually ready to deliver strikes against coastal objectives and accomplish missions in support of the ground forces. The aircraft carriers and missile vessels of the aircraft carrier attack large unit (AUS) must be evaluated as primary objectives, the destruction of which has independent operational consequences and, in addition, decisively affects the accomplishment of missions of a fleet in the support of the ground forces. In general, the mission of destroying an aircraft carrier attack large unit requires the execution of an independent operation of a fleet in coordination with long-range aviation, missile troops, and forces of the neighboring front.

As we have already noted, the accomplishment of the mission of destroying an aircraft carrier attack large unit in closed sea theaters has a number of intrinsic peculiarities. The military-geographic conditions make it possible not only to defend the aircraft carriers with the forces of the aircraft carrier attack large unit itself, but also to use for this, in full measure, the entire antiaircraft defense system of the member countries of NATO, as well as the system of antisubmarine defense created in advance, based on the equipment of the fixed facilities of the border and of the mobile forces. The heavily interrupted nature of a theater (the presence of island and reef areas) facilitates the massing of enemy vessels and hampers

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

their detection. All this makes it possible for the enemy, without particular risk, to concentrate aircraft carriers at considerably shorter distances from our seacoast and to deliver sudden strikes against considerably more distant (by 400 to 500 kilometers) rear area objectives than in open sea theaters. This thesis is borne out by the experience of the exercises of the U.S. Sixth Fleet in the Mediterranean Sea.

Thus, in closed sea theaters it is necessary to consider two possible alternatives of aircraft carrier attack large unit opeations: first, when an aircraft carrier large unit is concentrated before the initiation of combat operations in island areas which are at a distance of 1,000 to 1,200 kilometers (in certain cases perhaps even less) from our seacoast, and second, when an aircraft carrier attack large unit moves up from remote areas of a sea theater to deliver an attack at the operating radius of its aviation.

In the first case, the possibility of delivering a strike against the aircraft carriers before they launch their aviation is unlikely. The main mission of a fleet will be to deliver a counterstrike within the shortest possible period of time for the purpose of destroying the aircraft carriers and preventing repeated use of the aircraft carrier aviation.

In the second case, i.e., when an aircraft carrier attack large unit moves up from remote areas of the sea to the boundary of launch of its aviation, the mission is to deliver a strike against the aircraft carriers before the initial launching of the strike aviation. In spite of the fact that the conditions of closed sea theaters provide ample opportunity to employ refueling of aircraft carrier aviation in flight or at airfields on land, one must conclude that the most advantageous alternative for the enemy, ensuring the secrecy of operations, is to launch his planes from distances which allow them to fly to the objective of a strike without intermediate refueling.

The possible launching limit of aircraft carrier aviation for delivering attacks against probable objectives without intermediate refueling must be considered as the nearest boundary of that area in which it is necessary to concentrate

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the main efforts to destroy the aircraft carrier attack large unit (to deliver the main strike). The far boundary of that area can be defined as the maximum distance at which it is possible to deliver a massed strike by the most powerful forces against the aircraft carrier attack large unit. We support the opinion, expressed by many writers, that the most advantageous method of operations against an aircraft carrier attack large unit, considering its high mobility, is the delivery of a single strike which is as powerful as possible, primarily with nuclear-missile weapons, within the shortest possible period of time after the detection of the aircraft carrier attack large unit by reconnaissance.

Since, as a rule, aircraft carrier attack large units in closed sea theaters operate as separate strike groups (AUG), against which attacks can be delivered either simultaneously, or in sequence over short intervals of time, or, finally, with a considerable gap in time and place, the goal of each strike must be the destruction of one aircraft carrier. Consequently, the goal of the operation can be achieved by the delivery of at least two strikes, ensuring the destruction of both aircraft carriers.

The mission of destroying aircraft carriers can be accomplished by the joint efforts of missile aviation (the air forces - VVS - of the Navy and long-range aviation) and submarines. The missile troops of the Supreme High Command (VGK) can be used mainly for the destruction of aircraft carriers and servicing forces at bases. The forces of a front (missiles of tactical - takticheskoye - designation, fighter-bomber, and reconnaissance aviation) can be enlisted to support the combat operations of missile aviation and submarines.

For the conduct of combat operations against aircraft carrier attack large units at sea during the first days of a war, aviation will have the greatest use. Later on, as nuclear torpedo or missile submarines enter a sea theater, the role of submarine forces in the destruction of aircraft carrier attack large units will increase to a level of equal importance with missile aviation. To destroy an aircraft carrier attack large unit having a powerful antiaircraft defense which is echeloned

[redacted]

1.3(a)(4)

in depth, it is necessary to deliver concentrated strikes by missile aviation forces using cruise missiles with nuclear warheads (snaryazheniye). Since the explosion of only one missile with a nuclear warhead hitting the calculated point is sufficient to destroy any class of vessel, the expenditure of such missiles will be only one fifth or one sixth of the expenditure of missiles with conventional warheads.

Considering the vulnerability of cruise missiles to antiaircraft artillery (ZA) and antiaircraft guided missile (ZURS) fire, it is advisable to employ salvo launching of missiles in delivering strikes against a strongly defended objective. In view of this, the invulnerability to jamming of cruise missiles has great importance, permitting the use of a large number of them in each salvo. According to calculations, the destruction of one aircraft carrier operating as a component of an aircraft carrier attack group (allowing for the opposition of the antiaircraft artillery of the vessels and four two-missile salvos of antiaircraft guided missiles) can be accomplished by one salvo of six airborne (aviatsionnaya) cruise missiles with nuclear warheads launched at a distance of 200 to 220 kilometers from the aircraft carrier attack group. With a strike by six-missile salvos from two directions simultaneously, the destruction of two large vessels (an aircraft carrier and a cruiser) of an aircraft carrier attack group can be accomplished. In this case, of the twelve missiles launched in the two salvos, it is sufficient to have only six or seven missiles with nuclear warheads, and the other five or six missiles can have conventional warheads without causing substantial degradation of the results of the strike (the loss of delivery aircraft en route is not allowed for here).

A somewhat different picture is presented with the use of "Komet" missiles, which are vulnerable to jamming. In this case, in view of the impossibility of a salvo launching of the required number of missiles from one direction, increasing the density and reducing the depth of the combat formation of the delivery aircraft is achieved by organizing it into several parallel columns (waves), and also by launching two or more missiles on the beam (v luche) of one leading delivery aircraft. An indispensable condition for increasing the density of the strike is to attack from several directions. The experience of combat training confirms practically

[redacted]

1.3(a)(4)

the feasibility of launching "Komet" missiles from several directions, 45 to 60 degrees apart. Calculations show that in an attack from three or more directions the probability of the "Komet" missiles reaching the target increases to 25 percent, as against 10 percent in an attack from one direction.

To deliver strikes beyond the limits of a closed sea, missile-carrying aviation must overcome the antiaircraft defense while flying over enemy territory. Considering this, it is necessary to select flight routes over areas which are less saturated by the forces and facilities of the antiaircraft defense and to neutralize these forces and facilities in the zone of flight to the extent possible. However, considerable forces and facilities are required to neutralize the antiaircraft defense, so it can only be fully accomplished by the joint efforts of a fleet and a front. Along with the use of front missiles and fighter-bomber aviation, the facilities of radio countermeasures (radioprotivodeystviye) have primary importance in overcoming the antiaircraft defense, particularly in neutralizing the system of radiotechnical surveillance of aircraft (vozdushnoye radio-tekhnicheskoye nablyudeniye) and the control facilities of the enemy.

In addition to carrying out the supporting measures mentioned above, in order to overcome the enemy antiaircraft defense system (both the land antiaircraft defense system and the antiaircraft defense system of the aircraft carrier attack large unit itself), it is necessary that all branches of aviation make maximum use of low flight altitudes, right down to hedgehopping. We believe that flight at minimum altitudes must be maintained by strike groups of aircraft both over the sea and over enemy territory, insofar as local terrain permits. Taking on altitude should be done only when the objective of the strike has been approached to within limits ensuring the possibility of launching and guiding (navedeniye) airborne cruise missiles.

Regardless of the limited number of submarines which can be counted on beyond the limits of a closed sea during the first days of a war, they must be used not only for strikes against enemy vessels but also for carrying out reconnaissance. From the beginning of combat operations, when reconnaissance information

[redacted]

1.3(a)(4)

will be particularly needed for the delivery of an immediate counterstrike against the enemy, submarines may turn out to be the only reliable means of reconnaissance beyond the limits of a closed sea. At the same time, after detecting an aircraft carrier attack large unit and reporting it, submarines must use every opportunity to deliver nuclear strikes against the enemy aircraft carriers. Considering this and the complexity of resupplying ammunition, the maximum possible number of torpedoes on submarines should have nuclear warheads (with the exception of a certain number of antisubmarine torpedoes and torpedoes for firing at antisubmarine vessels).

In addition to the submarines deployed on the approaches to narrows, it is advisable to deploy the remaining submarines in small groups (two to three submarines each) along a wide front on the approaches to the probable combat maneuvering areas of the aircraft carriers. Such a disposition of submarines (PL) makes it possible to direct one to two groups of submarines of a brigade of submarines against the enemy in practically any direction he moves. Of course, in this case, only a small number of submarines sally forth to the attack, but the use of long-range torpedoes with nuclear charges compensates to a certain extent for the small number of attacking submarines.

It is advisable to use atomic submarines armed with torpedoes only for strikes against large enemy vessels. It is advisable to assign to them waiting positions outside the limits of the zone of probable movement of the aircraft carrier attack large unit, because the forces of the enemy antisubmarine defense (PLO) will carry out their most intensive search for submarines in that zone. In delivering strikes, atomic submarines, using their great underwater speed (50 to 60 kilometers per hour), approach the aircraft carrier attack large unit (AUS) on the basis of reconnaissance information, with the design of delivering the strike from the bow angles (nosovoy kursovoy ugol) of the enemy. In this case submarines can launch nuclear torpedoes against the vessels of the aircraft carrier attack large unit from distances of 15 to 20 kilometers, without penetrating the curtains of distant and close vessel protection of the aircraft carriers. On the other hand, when delivering

[redacted]

attacks from astern, a submarine must approach to within a distance of 4 to 5 kilometers of the enemy vessels. Both for self-defense and in the interest of combating enemy missile-carrying submarines, atomic submarines must destroy every enemy submarine detected, and to do this they must have reliable antisubmarine weapons and equipment for the detection of submarines.

The positions for missile submarines must be chosen with the design of carrying out a shift (manevr) of trajectories of the cruise missiles which will cover the largest number of probable directions of enemy movement. Considering the necessity of salvo firing, missile submarines are most advisably employed in groups, ensuring the launching of six to eight cruise missiles in one salvo. According to calculations, in this case, in the delivery of a strike against an aircraft carrier attack group (AUG) of typical composition, it can be guaranteed that one of the missiles with a nuclear warhead will reach the target.

The most crucial problem in organizing such a strike is providing the missile submarines with accurate data on the location and factors of movement of the enemy for calculating an aiming point which ensures the lock-on (zakhvat) of the enemy vessels by the homing system of the missile. With clear-cut organization of the control of submarines and aviation, this task can be accomplished by aviation carrying out a thorough reconnaissance (dorazvedka) of the enemy. Also exerting great influence on the success of the firing is the accuracy with which the submarines determine their own position; this can be ensured by the use of radio navigation systems of high accuracy and by further improvement of the navigational instruments on submarines.

As basic measures for the support of combat operations of submarines beyond the limits of a closed sea, the following must be provided for: strikes by missiles against the coastal centers of the antisubmarine defense, destruction of aircraft carrier antisubmarine hunter-killer groups at sea by the forces of aviation, and measures for self-defense by the submarines.

Obviously, in operations for the destruction of enemy forces at sea, the greatest effect can be achieved if there is

[redacted]

tactical coordination between submarines and aviation. However, considering the high mobility of aircraft carrier and missile vessel formations, as well as the complexity of achieving tactical coordination, delay in the delivery of strikes, for the purpose of assemblying all forces at assigned positions or by a specific time, cannot be tolerated. The power of each strike group enables it to inflict defeat upon the enemy even when the planned sequence is not observed.

What has been said does not signify a denial of the necessity of coordination. The point is only that under the conditions of the employment of missile-nuclear weapons, the most important thing is to anticipate the enemy. If the situation allows, i.e., the enemy operates in accordance with an alternative which was allowed for in planning, or close to it, then, undoubtedly, the best results will be obtained by combat operations carried out in the most expedient order. Specifically, the following sequence of strikes against an aircraft carrier attack large unit can be recommended as one of the advisable alternatives. First, missile submarines deliver a strike, since these forces ensure the greatest surprise of a strike because of the low flight altitudes of cruise missiles. After this, exploiting the weakening of the antiaircraft defense of the enemy large unit as a result of the strike of the submarines, missile aviation delivers a strike. Torpedo submarines attack last, getting a chance to use their weapon most effectively against a disorganized enemy. In a particular case, the strikes of aviation and torpedo submarines may coincide in time. In such a case, to ensure mutual safety, aviation must use only nuclear airbursts and submarines must use only underwater bursts.

It is quite obvious that success in combatting an aircraft carrier attack large unit depends entirely on reconnaissance, especially aerial.

For the fulfilment of the missions of aerial reconnaissance, it is necessary, in our opinion, to enlist simultaneously considerable groups of aircraft, which must, in a narrow sector and at low altitudes, surmount the zone least saturated with the forces and facilities of antiaircraft defenses and then disperse in accordance with their assigned reconnaissance routes. For the detection of an aircraft carrier large unit, not only the forces

of naval reconnaissance must be used, but also the reconnaissance of the missile troops of the Supreme High Command and of long-range aviation.

Support of the ground forces in a maritime area. Without examining all of the above-mentioned missions which might be accomplished on behalf of a maritime front, we shall dwell briefly only on the fundamentals of accomplishing the task of disrupting the entry of enemy naval forces through the straits.

As is well known, the operational situation in closed seas depends to a considerable degree on the possibility of the entry of enemy naval forces from outside. In view of this, fleets in closed theaters have always had the mission of interdicting or disrupting the entry of forces of an enemy fleet through the straits. The importance of this mission rests in the fact that its accomplishment supports to the greatest degree the success of the operations of the ground forces in maritime areas, and creates favorable conditions for the opeations of the forces of a fleet in fulfilling other missions in the closed seas.

The essence of the mission under examination is defined by the requirement that the enemy formation be destroyed before its passage through the straits, and that individual groups penetrating through the straits be destroyed in the area adjacent to the straits, i.e., before the accomplishment of their missions. Depending on the general situation and the composition of the enemy forces, this mission can be considered as one of the individual missions of support of the ground forces, and be accomplished in the course of daily operational activities, or it can be considered as a fundamental mission of support and be accomplished by carrying out an offensive operation for the destruction of the forces of the enemy fleet.

We believe that, in a number of instances, it will be impossible to differentiate sharply the mission of disrupting the entry of enemy naval forces through the straits and the mission of destroying his forces in the straits zone and beyond its limits, since it will not always be possible to determine what the enemy will elect to do, to send his forces through the straits or to operate them on behalf of his ground forces located outside the closed sea. Obviously, there will be instances when one will

occur and instances where the other will occur. Therefore, the conduct of an offensive operation for the destruction of the enemy forces, and not a defensive operation, is in order. This fits the conditions of the initial period of a war, during which, as is known, in addition to pursuing the immediate goals of this or that operation, one must always pursue the goal of seizing the initiative, which has a decisive influence on the entire course of combat operations during that period.

In the final analysis, in determining the conditions for mounting a given operation during the initial period of a war, we do not see the necessity for detecting without fail concrete indications of the intentions of the enemy to send his forces through the straits. Moreover, it is not always possible to do this sufficiently ahead of time. It seems to us that the operation under examination should be carried out from the very start of combat operations and should have the character of a counterstrike for the purpose of destroying the main enemy strike (or landing) formations, detected even before the start of combat operations. In this case, irrespective of the intentions of the enemy for the use of his forces, the goal of the operation is attained by their destruction.

In general, to achieve the goal of the operation, accomplishment of the following particular tasks must be provided for:

- the destruction or weakening of an enemy formation detected at its bases;

- the destruction of the main enemy forces at sea, including in the straits zone;

- the destruction of units of forces which have penetrated through the straits in the area adjacent to the straits.

In setting forth the particular tasks in such a sequence, we do not mean that it is required to fulfill all of them without fail. The point is that they must be considered during the planning of the operation. It is not difficult to imagine various alternative situations in which it will be unnecessary to accomplish this or that particular task.

Speaking of the destruction of enemy vessels at their bases, we have in mind those bases and points of basing which are located within the limits of the straits zone or in the area just outside the straits. In accomplishing this mission in closed sea theaters, the main role belongs to large units of ballistic missiles of operational designation of the ground forces, missile submarines, and coastal missile units of the Navy. Each of these arms of forces can deliver strikes against vessels at their bases either independently or in coordination with each other. By this, not only are the enemy vessels at the bases destroyed, but also the naval base or point of basing itself is either destroyed or put out of operation for a long time.

The use of ballistic missiles provides a number of advantages because they are less subject to dispersion (rasseivaniye) in comparison with cruise missiles and are invulnerable to the forces and facilities of the enemy antiaircraft defense. Therefore, in fulfilling the mission by joint efforts it is expedient to plan the delivery of the first strike by ballistic missiles, pursuing the goal of not only delivering destruction to the enemy vessels and the installations of a base, but also of neutralizing the forces and facilities of the enemy antiaircraft defense, thus decreasing significantly the counteraction to the subsequent employment of cruise missiles from submarines and coastal launchers.

In using cruise missiles, it is necessary to allow for the fact that because of their low flight altitudes their use for strikes against objectives remote from the seacoast is limited by the nature of the local topography. Specifically, the altitude of the terrain in the zone of flight of cruise missiles must not exceed 200 to 300 meters above sea level. In this respect, coastal missile units of the Navy are more limited in the selection of possible directions and distances of fire than submarines, which can select the most advantageous direction of fire by changing the launching position. On the other hand, submarines are inferior to coastal missile units in accuracy of fire, since the error in determination of the location of the submarine is added to the dispersion of the missiles. In closed seas, with the existing means of supporting the navigation of submarines, this error in location may amount to one to four kilometers. Considering

[redacted]

1.3(a)(4)

these circumstances, it is necessary to use ballistic missiles for the destruction of objectives more remote from the coast, and cruise missiles for the destruction of coastal objectives.

In planning combat operations for the destruction of vessels at sea, it is necessary to distinguish between two cases. If the vessels are effecting movement in long and narrow straits, then cruise and ballistic missiles can be used successfully for the destruction of the vessels. If the enemy vessels are located outside the straits and have freedom of maneuver, then it is not advisable to use either cruise or ballistic missiles with inertial (avtonomnoye) guidance, since during the time of preparing the missiles for launching, the vessels can change the factors of their movement sharply, and by the moment of the strike be beyond the limits of the radius of destruction. In this case, the vessels can be destroyed by naval attack aviation, using missiles and nuclear bombs.

The delivery of joint missile strikes against enemy vessels forcing the straits requires very careful organization, especially the organization of reliable reconnaissance, and timely preparation and precise direction of fire. The organization of missile strikes in the straits zone must provide for determination of the limits for detection of the enemy (with consideration of the readiness of the missiles for launching) and for designation of the positions and time for delivering the strikes. During successive strikes, to avoid mutual interference (pomekh) during the flight of the missiles, each strike group must be assigned aiming points and a time of attack, i.e., a moment of firing (vzryv) the missiles. The time of launch for the missiles is calculated on the basis of the assigned time periods of a strike, with allowance for their flight time to the target.

Considering the substantial differences in the nature of the preparation and methods of fire of forces participating in a strike, it is impossible during the course of a strike to shift the aiming points and introduce some sort of adjustments requiring changes in the initial data for firing. This leads unavoidably to disruption of a strike. Thus, the calculated area of a strike, positions, and aiming points, and consequently all of the initial data for firing, remain unchanged. As a rule, the conditions of straits make it possible to control the forces precisely, changing only the time of the strikes in accordance with the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

speed of movement of the enemy. These conditions also determine the paramount role of reconnaissance, as the success of a strike depends primarily on the trustworthiness and accuracy of its information.

Shifting the area of a strike is possible and necessary only in case the enemy breaks off forcing the straits and puts into his bases (into his roadsteads). It is to be supposed that in this case there will be sufficient time for shifting fire, especially if the probable holding points of the enemy are taken into account in advance and specified to the commanders of large units and units as alternate strike objectives.

Successful operations of our forces beyond the limits of a closed sea do not exclude the possibility of a penetration through the straits by individual enemy groups, for the destruction of which a special formation of forces must be deployed in advance. In the composition of this formation, coastal missile units of the Navy can be effectively used; they would deliver the first strikes against the enemy formation while it is still in the straits, and then destroy the enemy vessels which have penetrated into the area adjacent to the straits. An important advantage of coastal missile units is the ability of the duty sub-units (dezhurnoye podrazdeleniye) to deliver strikes against an enemy appearing unexpectedly in shorter periods of time than can any other naval forces. For carrying out combat operations for the destruction of enemy forces which have penetrated through the straits, other naval forces must also be enlisted, especially submarines and surface missile vessels. Of primary importance for the successful accomplishment of the mission by submarines is their deployment in advance in the area adjacent to the straits, ensuring their timely maneuver for the interception of the enemy suddenly sallying forth from the straits.

It should be noted that the conditions of a closed theater, primarily the feasibility of carrying out overlapping reconnaissance by various forces, and also the possibility for ample utilization of coastal facilities of surveillance, facilitate the organization and practical accomplishment of coordination of all forces, and make it possible to deliver strikes against the enemy in the most advantageous sequence.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Such are some of the elements of the accomplishment of the mission of disrupting the entry through the straits of the naval forces of the enemy. The growing operational-tactical potential of the forces, based on the power of missile-nuclear weapons, makes it possible to accomplish such a mission, not by blockading the straits from the side of the closed part of the theater, but by destroying the enemy forces at their bases and at sea beyond the limits of the closed part of the theater.

In the present article, methods of using naval forces in closed sea theaters in the initial period of war have been examined only in general outline and inconformity with the situation in these theaters at the present time, with consideration of the prospects for the next few years. In conclusion, it should be noted that the special complexity of this situation, caused by the limited dimensions of the closed sea theaters and the presence in the immediate proximity of bases for aggression prepared in advance on the territories of the member countries of NATO, urgently requires all possible automatization of the control of naval forces, above all, the automatization of the collection and processing of information.

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "The Nature of Modern Armed Combat and the Role and Place in It of the Various Branches of the Armed Forces", written by General of the Army Pavel A. Kurochkin, Chief of the Military Academy i/n Frunze.

The article appeared in the 1960 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. The month of publication of the 1960 Second Edition is unknown. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

The Nature of Modern Armed Combat and the Role and Place in It of the Various Branches of the Armed Forces

by

General of the Army P. Kurochkin

The concept of creating a special Collection of articles of the journal Military Thought (Voyennaya Mysl), for the purpose of presenting an opportunity to the leaders of the Armed Forces to exchange ideas freely and to discuss the most important problems of modern (military) art is timely and unquestionably useful. This is confirmed, at least, by the worthy and keen analysis of questions, and the decisiveness, with which the first authors of the Collection are coming forward. A discussion that starts in this fashion is headed for sharp and fundamental disputes, promising a fruitful denouement.

In the articles found in the first Collection, many new positions on the nature of modern warfare are brought up, as well as methods and forms of conducting armed combat, and regarding the employment of the branches of the armed forces in it. We shall dwell upon individual questions brought up by Colonel-General A. Gastilovich in his article, and also in the articles of Lieutenant-Generals I. Tolkonyuk and V. Baskakov that touch upon the same questions in many ways.[1]

Is Soviet Military Art Undergoing a Crisis?

Common to the articles of Generals Gastilovich, Tolkonyuk, and Baskakov is their position that there is a discrepancy between our military art and the new conditions of nuclear warfare; regarding this, they state that it is necessary to make a bold reappraisal of our entire military doctrine, strategy, operational art, and tactics in particular. The authors of the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

article speak unequivocally of a crisis which they claim Soviet military science and military art are undergoing.

"We", says General Gastilovich, "are undoubtedly trying to squeeze missile-nuclear weapons into the framework of the old, habitual position of our military doctrine, only modernizing the latter slightly, and we forget that this doctrine was formulated on the basis of the employment of means of armed combat that are basically different from present-day means and cannot be compared with them" (page 6). "The matter does not go beyond the adaptation of the old forms and methods to the new conditions, while it should be a matter of completely new categories in military affairs. Apparently the time has come to sacrifice, boldly, many of the positions on which the basic principles of operational art and tactics are based" - in this way, General Tolkonyuk supports Gastilovich. "This is a clear contradiction of the theory of operational art and can be called a crisis without exaggeration", - thus General Baskakov would summarize the matter.

These are not just words; the posing of the question is sharp and, at first glance, basic. However, upon deeper examination one finds that the authors put things on the agenda that have been raised already and even partially settled. In our opinion, there is no basis for speaking of a fundamental reassessment of Soviet military doctrine, nor of a crisis in military art. For our military doctrine has already been reexamined with the introduction of atomic weapons, and that which is viewed as a "crisis" in military art is nothing more than the natural expression of the contradictory and surging development of military affairs.

Indeed, of which attempts to squeeze missile-nuclear weapons into the framework of the old positions of our military doctrine, of what "slight" modernization of this doctrine, are they talking about, when the very opportunity for the statement of Comrade Gastilovich arose only as a result of the formulation of new doctrine, completely different from the old one. It is paradoxical that Comrade Gastilovich bases his judgements on the re-examination of doctrine on the positions of the new doctrine formulated in addresses and speeches of N. S. Khrushchev, and in the speeches and orders of the USSR Minister of Defense, Marshal of the Soviet Union Malinovskiy,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

and other government and military leaders.

Soviet military-scientific thought did, for a certain period of time, follow the path of partial modernization of the old doctrine, in order to lessen to some extent the impact of nuclear weapons on the established forms and methods of armed combat. But this evolved naturally from the objective conditions prevailing at the time, determining the possibilities of military-scientific thought. However, it should be stated that, to a certain extent, everything that was done during this period helped to develop Soviet military science and military art, and laid the groundwork for going on to the next higher step of their development for the creation of a new military doctrine.

The establishment of a completely new doctrine based on the employment of missile-nuclear weapons in armed combat was a comparatively long and complicated process. The final formulation of this doctrine could be put on the agenda only after the creation of the actual materiel prerequisites, which determined not only the development of the axes of the use of missile-nuclear weapons, but also the assurance of qualitative advances in its development, in the form of achieving unlimited range and accuracy in the destruction of targets, as well as the quantitative accumulation of nuclear weapons and the means of delivering them.

The stockpiling of nuclear-missile weapons in adequate quantities affected the characteristics, methods, and forms of modern armed combat profoundly. This was reflected in the new Soviet military doctrine and "the novelty of modern warfare and its dissimilarity with past wars".

Led by the new military doctrine and corresponding directives of the Party, the Government, and the higher military command, Soviet military-scientific thought began to clarify and define the laws and principles which have to be incorporated into the basis of armed combat at its present stage, and to search for new methods and forms of this combat, taking into consideration the nature of the political goals of the opposition's coalitions and the existing materiel base.

This process is nothing more than a re-examination of the theoretical views that have accumulated regarding the conduct

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

of a war and military actions of all dimensions, training, organization, and equipping of the armed forces. But this is not a bald and pointless repudiation of all previously accumulated experience of armed combat. In Lenin's philosophical notebooks the dialectical nature of repudiation is brought out as follows: "Not a bald repudiation, not a random repudiation...is characteristic and essential in dialectics...but a repudiation, as a feature of communication, as a feature of development, with the retention of the positive...." (V. I. Lenin. Filosofskiye tetradi, 1947, page 197).

To speak of a crisis of military art in these circumstances--willingly or unwillingly, signifies the downgrading of the importance of a huge amount of work already carried out in this direction, and closing one's eyes to the actual situation, in other words, misunderstanding the crux of the process which is going on.

Without a doubt, the completion of a new qualitative advance, and the elevation of Soviet military science to a new level of development which answers modern requirements, involve certain "growing pains". What is required is a reappraisal of the old with a decisive rejection of everything that is of no value, and the blazing of new trails. All this is connected with overcoming the occasionally stiff resistance of various kinds of conservatives, who actually are inclined to substitute the renewal and modernization of old experiences, above all the experience of World War II, for a decisive turn to new endeavors.

The problem before the leading representatives of Soviet military-scientific thought is to clarify the new military doctrine and mobilize all our forces to fulfill the programmed directives of the Party, the Government, and the Minister of Defense to assure a new advance in the development of military science. This problem is within reason and, without a doubt, will be fulfilled in a very short time. During this struggle unprincipled conservatism will be defeated, as will harmful talk of many kinds about stagnation and crisis in Soviet military science.

Against a One-Sided Approach to the Solution of the Question of the Nature and Forms of Modern Armed Combat.

The basic thesis of the articles of Generals Gastilovich, Tolkonyuk, and Baskakov is the affirmation of the paramount

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

role of nuclear-missile weapons in all aspects of the combat activity of the armed forces. General Gastilovich writes: "Under modern conditions, groupings (obedineniye) of missile troops of the Supreme High Command (VGK) with their unlimited range of action and the tremendous force of their firepower have become the main and decisive branch of the armed forces... The efforts of all other branches of the armed forces...have to be directed towards the most rapid and effective utilization of strikes by the missile groupings of the VGK. Besides, the basis for planning the actions of each branch of the forces is also based on their use of their own missile-nuclear weapons, and not on the number of divisions, ships, aircraft, etc." (page 7). On page 11 he comes to the conclusion that in his "concept, the main, leading role belongs to the operations of the missile groupings of the VGK, but not for the purposes that we usually visualize them now. This is not combat with the nuclear means of the enemy, nor the weakening of his economic potential, nor combat against the reserves, etc., but the complete destruction of the enemy with nuclear weapons of megaton range against a vast territory, eliminating entire countries from the war."

I. Tolkonyuk states: "There is good reason to believe that often the will of the enemy to resist can be suppressed only by strikes of nuclear-missile weapons" (page 21). We find this in General Baskakov's article: "Nuclear weapons should be considered and employed as independent and decisive means for destroying the enemy" (page 32). It should be noted that the statements of the first two authors refer largely to the general strategic aspect, and the third--to the field of operational art. But this does not change the substance of the formulation of the question.

If we follow the concepts developed by the authors of the articles mentioned, and doubtless agree that nuclear-missile weapons should have the decisive role in assuring the possibility "of conquering in a short time", in a way, on the whole, or to achieve success in any operation, everything else seems relatively simple. It is only necessary to supply the missile troops with adequate means, provide the necessary nuclear-missile means to the ground forces and other branches of the armed forces, review certain aspects of our military strategy and operational art, and thus are created the conditions for successful resolution of the course and outcome of all armed combat.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Guided by this premise, General Gastilovich offers a fairly simple plan of action (a variation of the concept for the European theater). In this plan a countering nuclear-missile strike is made against two or three NATO countries with the purpose of "total destruction of the enemy" and the elimination of these countries from the war. In order to utilize the results of this strike, the ground forces are put into operation; thirty to forty various ground forces division quickly "finish off" the remaining forces of the enemy in the border area, and at a rapid rate they conquer the zones that have to various degrees been destroyed and contaminated by radiation produced by the massive strike of the strategic missiles, and occupy the country.

Besides, "if after the conquering of the territory of the countries that were subjected to the first massive nuclear strike, the enemy does not capitulate, then a similar all-destroying blow may be repeated against the next country." The substance of the variations of actions proposed by the author amounts on the one hand, to the complete destruction of the enemy and withdrawal of a country from the war, and on the other hand, to the conduct of operations of the ground forces in order to overrun the destroyed and contaminated zones, the suppression of any remaining resistance, and the occupation of the country.

In our opinion, the concept presented has many contradictory features. In the first place, the concepts "total destruction of the enemy" and "eliminate a country from the war" mean the end of all resistance, and capitulation of the countries. But once this is so, what major operations by significant elements of the ground forces can we talk about under these conditions? Why throw in thirty to forty divisions with the purpose "mainly of conquering rapidly the zones that, invarying degrees, have been destroyed and contaminated by radiation"? One does not need much of a flair for fantasy to imagine what these troops will encounter in a country that has been subjected to a nuclear-missile strike "for complete annihilation". Panic, chaos, masses of dead and mutilated persons, and the ruins of the destroyed cities will exert a deleterious influence on the troops. The same conditions will oblige the troops to undertake the incredibly complicated tasks of establishing order, carrying out rescue - rehabilitation (spasatelno - vosstanovitelnaya) work, organizing relocation, rendering medical assistance, and providing rations for large

[redacted]

1.3(a)(4)

masses of people. At the same time, the troops themselves will be exposed to irradiation and contagion and many complicated problems affecting them can arise, which will not be so simple to solve. The questions of billeting, supply, medical and sanitation services, and others will become extremely complicated, and sometimes they will simply be insoluble.

Having taken the concept proposed by the authors as a basis, we cannot avoid falling into an insoluble argument concerning the place they assign to nuclear-missile weapons, and the role of the ground forces and the other branches of the armed forces. This conception leads to the repudiation of any significant place for the ground forces, and in fact abolishes all branches of the armed forces except missiles; it abolishes strategy, operational art and tactics, and joint actions by the branches of the armed forces and the arms of troops composing them which have been studied and established.

What are the reasons why the conception developed by Generals Gastilovich and Tolkonyuk is groundless?

First of all, it is impossible to combine the incompatible. One cannot speak of the possibility of "total destruction of the enemy", of the possibility "of crushing his capability and will to resist", of the elimination of entire countries from a war by nuclear-missile weapons alone, on the one hand, and the necessity and possibility of conducting on the territory of these countries large-scale and vigorous operations of the ground forces on the other hand.

Second, and most important, the solution of the problem must be sought only through a thorough evaluation of the situation, which is possible only by taking the political factors into account along with the materiel factors. The content of the new Soviet military doctrine orients our military thought towards exactly this kind of approach to the solution of questions.

In fact, our new military doctrine is based on the paramount role of nuclear-missile troops and provides for the carrying out of decisive nuclear-missile operations. Our nuclear-missile troops are capable of erasing from the face of the earth any country or countries attacking us or other Socialist states.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

However, this basic premise stems only from the possibility of such a destructive war being unleashed by a frantic clique of imperialist lunatics who are in power. In this case, we have to be ready to deliver the most destructive blows against the instigators of the war.

Herein we cannot escape the fact that the bastion of those who inspire this policy of playing with fire is beyond the confines of the European continent; so, in the event of the unleashing of a war, the main efforts of our Armed Forces, first and foremost of the chief component - the missile troops - will be directed primarily against the decisive element of the enemy coalition. Here too, however, the question can only lie in the plan to defeat the enemy quickly and completely and eliminate his capability to continue active military operations. This is the basic and the most complicated task facing our missile troops. It has to be solved in the shortest possible time, with maximum use of the effectiveness of nuclear-missile weapons.

The success of the outcome of this operation (operations) of the missile troops will depend on a series of circumstances, above all, on the selection of the proper moment to inflict a strike on the most vitally important enemy centers, primarily on his centers of nuclear-missile weapon production and inter-continental-missile launching bases. The result of the operation must be the ruination of the military and governmental machines of the aggressor. A blow of exactly this type can also cause other partners of the enemy coalition to give very careful thought to the advisability of entering the war. But an indispensable condition of complete victory must be the readiness of the missile troops to carry out one or more operations against some of the countries of Europe and other continents. We have in mind the countries that will undertake to follow their senior partner into the war. The intensity of the reaction must fluctuate, depending on the nature of the actions of the armed forces of one country or another.

In the determination of the degree of reaction it is necessary to consider that nuclear-missile weapons must be used in a decisive and purposeful way, but only within the limits of expediency. The forsaking of this requirement can lead to a situation wherein a war unleashed by aggressors will involve such

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

large human and material losses on both sides that the consequences may be catastrophic for mankind.

In one case it may be necessary to conduct operations for the complete destruction of the means of retaliation, and in another--to destroy the strategic nuclear weapons bases. It is clear that in a strategic situation of this type it may be possible to find a place for the utilization of the other branches of the armed forces of the Soviet Union, and of the forces of other countries of the Socialist camp.

We are also inclined to think that, in some cases and in some directions, the primary role will belong to ground forces equipped with nuclear-missile weapons. This can occur in the unfolding of events when, after execution of the countering nuclear-missile operation against the main bulwark of the imperialist bloc, or simultaneously with it, a strike is delivered against a group of objectives in the countries which allowed the use of their territory by their senior partner for the launching of the first blow. This strike will not have the purpose of "complete annihilation of the enemy" in the sense that General Gastilovich uses it. The strike is calculated to disorganize the governmental control and destroy the main strategic and operational nuclear weapons bases, as well as the main formations of enemy troops. In order to achieve the results desired of the operation, the ground forces will carry out joint operations with the air forces and the navy for the complete destruction of the armed forces of the enemy and the achievement of the ultimate goals of the war. The ground forces, with their mobility and tremendous firepower, are aiming in decisive directions - the seizure of key positions of a country, possession of which will decide the outcome of the campaign in a given theater.

The directions of troop actions are stipulated in the overall scheme of a campaign. In addition, an effort should be made to avoid troop operations in areas where the terrain is highly contaminated by radioactivity arising as a result of our own strategic nuclear-missile strikes. The troops should use their own nuclear-missile weapon capabilities to support their operations. The expenditure of these means should be strictly limited and aimed at the destruction of enemy formations capable of disrupting or slowing down the successful development of attack in decisive

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

directions.

When necessary for the assurance of a correlation of forces favorable to our troops, the forces and means of VGK missile large units (soyedineniye) may carry out strikes upon receipt of requests for fire from a front and an army.

Thus, we consider that the dominant role in an operational-tactical plan will quite often belong to the ground forces, by dint of their being equipped with nuclear-missile weapons, and above all, to the highly mobile motorized rifle and tank large units.

In regard to the size of the Armed Forces, we consider that a large part of the adult population, capable of active participation, will be mobilized and used as needed to guard and defend the entire territory of the country. Among the special organizations, the rescue-rehabilitation detachments will play an important role.

Obviously, self-defense and guard units and large units, as well as rescue-rehabilitation detachments, have to be created in accordance with territorial criteria and be prepared in advance to fulfill their tasks.

However, the size of the regular ground forces will undoubtedly be large; in other words, without a massive army it is impossible to have rapid and definitive victory in a future war. It is particularly necessary to consider the colossal losses that the ground forces will suffer, which will require sizeable reserves trained for operations.

In connection with the great probability that under certain conditions of the situation it will be necessary for the troops to fulfill the tasks of occupation, we consider it necessary to give special emphasis to the importance and responsibility of this function of the troops and to the advisability of carrying out at least the most elementary training of the troops in this sphere. In the past there have been serious difficulties in this regard. Now, under the conditions of the wide use of nuclear weapons, it is necessary to surmount the serious complexities of the situation. The command of field troops is confronted with the necessity not

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

only of maintaining order among the troops themselves, but also of implementing measures for the organization and supervision of huge masses of people in a state of panic. It will be necessary to clear roads, to organize the evacuation of people from contaminated areas, and to provide huge masses of people with medical aid and food. To ignore these measures may lead to very drastic consequences.

Several Aspects of Operational Art

A new assessment of a number of questions of operational art by the authors of the special Collection is indicated, timely, and necessary. In the vanguard of these stands the solution of such questions as the place, role, and conduct of nuclear-missile operations in modern warfare, questions about the scale of modern front and army operations, regarding new principles of planning offensive operations, regarding the principle of concentrating the main efforts to destroy the enemy's nuclear means and main troop formations, regarding the creation of rescue-rehabilitation troops, and the working out of operations within military districts. A profound elaboration of these questions, on the basis of mass employment of nuclear weapons, will be a resounding contribution to the development of Soviet military science.

In this connection, it must be noted that the formulation of some of the questions, especially in the articles of Generals Gastilovich and Baskakov, in our opinion, are faulty. This applies particularly to the question of operational offense and operational defense, which we shall dwell upon.

The substance of the statements of Generals Gastilovich and Baskakov on this question amounts to the following: nuclear weapons eliminate the boundaries between operational offense and operational defense (page 37); in modern conditions offensive and defensive operations will be distinguished from one another mainly by the number of nuclear weapons allotted them (pages 12 and 15), in these operations the methods of troop operations will be identical (pages 15 and 37); defense, in the former meaning of the term, can only occur on a tactical scale (pages 14 and 37); the creation of defensive zones is impractical--any large unit executing defense in place will be destroyed by nuclear strikes by the enemy or will merely be bypassed by him (page 15); on an operational scale,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

defense cannot be stable (page 15).

Can we agree with such assertions? We feel that we cannot, primarily because these assertions do not conform with, and at times clearly contradict, Marxist dialectics in general, and the new conditions of conducting armed combat in particular.

In actuality, mass employment of nuclear weapons does change the nature of modern offensive and defensive operations radically. Large-scale maneuvering, aggressiveness, and decisiveness are now inherent to both an offensive and a defensive operation. Under modern conditions, an offensive operation will have more elements of defense and the defensive operation will have more elements of an offense. However, this has not made, and will not make, a defensive operation an offensive operation.

It does not follow that we turn our main attention to the similarity of offense and defense if we want to understand the substance of this contradictory phenomenon, but to their differences, to the study of the specific peculiarities of the opposing aspects, to the exposition and study of the major and minor aspects of this contradiction, without which it is impossible to develop the correct approach either to operational art or to tactics.

Obviously, we should not speak here of erasing the dividing line between operational offense and operational defense, but of the new nature of these conflicting aspects of armed combat, caused by the mass employment of nuclear weapons, and of the need to develop qualitatively new methods of conducting modern offensive and defensive operations. Talk of "erasing the dividing line" only leads us away from the solution of urgent problems of modern offense and defense.

It is likewise impossible to agree with the authors' declaration that modern offensive and defensive operations will be distinguished from one another primarily by the number of nuclear weapons allotted them.

The forces and means of the sides, whatever their quantity and quality, cannot in themselves determine the specific peculiarities of one or another type of combat operation. It is one thing to have plenty of forces and means (including nuclear weapons), but

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

quite another to defend oneself and, on the other hand, to start offensive actions when these forces and means are considerably less. An example of this is the battle at Kursk, where we had plenty of forces and means but were on the defensive, while on other fronts, where the forces and means were significantly less, we were taking the offensive.

The offense, as a rule, usually has comparatively greater forces and means than the defense. But who would say that in modern conditions it is impossible to attack and win with equal or even smaller forces?! Nuclear weapons indeed create more favorable conditions for the triumph of this concept of military art. But if this is so, the quantity of forces and means in general, and of nuclear weapons in particular, cannot serve as a criterion of the type of operation, because it cannot determine the characteristic and specific traits of one or another type of combat operation.

In our opinion, it is not the quantity of nuclear weapons which is the factor determining the identifying features of operations, but the targets and the nature of the combat operations, and the methods and ways in which they are carried out, insofar as they alone allow us to see the specific peculiarities of attack and defense, their substance. The authors ignored these factors and took as a foundation the incidental and transient, which led them to incorrect conclusions.

General Gastilovich, alluding to the fact that part of the forces of an army or front may take the offensive during a defensive operation, declares that defensive operations of a front and an army will resemble an offensive operation in their operational methods. General Baskakov adheres to more or less the same opinion, asserting that "the difference between the conduct of an offense and a defense....remains in the tactics alone" (page 37).

It is impossible to agree with such assertions. We always had elements of offense in our defense, but we never considered the operational methods of troops on offense and defense as a sign of equality. This must not be done now, as this will lead unavoidably to the glossing over of the specific traits of offense and defense, and to a one-sided and superficial scrutiny

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

of the complex phenomena of armed combat, with all the consequences that arise therefrom.

Defense has a clearly defined goal--to disrupt or stop (hold up) the enemy offensive, inflict sizeable losses on him, and create favorable conditions for going over to the offensive. And if it does not succeed in withstanding the offensive, it does not achieve this goal. The question arises as to why we have a defense which is incapable of stalling an enemy offensive, inflicting losses upon him, and effecting favorable conditions for our troops to go over to the offensive?!

Consequently, the defense has to be stable if we wish to achieve the goals; nuclear weapons cannot alter this requirement. It is a different matter that the stability of the defense under modern conditions need not be bound rigidly to holding whatever has become of the main line of resistance and the forward area. But this is a question of the development of new methods for conducting a defensive battle and operation.

The fact that the enemy, having nuclear weapons, is able to destroy the defense, break through the defensive line, or bypass the troops that occupy it, does not mean that defensive lines or areas are not needed, or that the defense cannot be stable under modern conditions. To speak of defense without defensive lines or areas is like talking about an offensive without an attack, without forward progress. If we approach this from the standpoint of the possibilities of nuclear weapons, it will be even easier for the offense to destroy or bypass enemy troops if they are in assembly areas.

Obviously, we should speak of another thing: what defense should be like under modern conditions, what the characteristics of a defensive line or area should be; how, where, and in what time periods defensive installations must be created, how to ensure the stability of the defense, how to safeguard personnel and combat equipment in the defense, and what methods of conducting a defensive battle and operation should be adopted in order to attain the goals of the defense.

In his article, "Mountain Warfare Then and Now," F. Engels, pointing out the validity of views on the impregnability of the so-called Swiss mountain redoubt, wrote: "Does this mean that

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

the defense of a mountainous country is completely useless? Of course not. It means only that the defense must not be merely passive, but should draw on its power and mobility, and operate offensively whenever an opportunity arises" (F. Engels Selected Military Works, Voyenizdat, 1957. page 99).

In other words, in conditions when the offense becomes stronger than the defense, the problems of the latter must be solved, not by abolishing the defense, but by developing new, more advanced methods of conducting it. Nuclear armament gives us every opportunity for doing this. In the hands of the defense it increases the stability of the defense immeasurably. Of course this will be a real defense, not one backed by some sort of thin defensive line of troops under cover, as General Baskakov recommends. It stands to reason that neither this line nor the defensive zone is capable of containing an enemy that is equipped with powerful nuclear weapons. Modern defensive battles and engagements will take place in large areas, along the front and in depth, and often in separate directions. For this reason, operational defense must be deep, and capable of resisting the powerful, dispersed strikes of the offense. This can be achieved by creating a system of defensive areas echeloned in depth, and also by dispersed disposition of the reserves along the front and in depth.

The basis of modern defense will apparently consist of holding defensive areas firmly in conjunction with obstacles, operating offensively wherever the slightest opportunity presents itself, and anticipating the enemy in the delivery of strikes. It is not difficult to imagine the gravity of the situation of the offense if the defense is able to stop it. Even a small number of nuclear strikes, against fairly dense, openly deployed combat arrays of the offense, can inflict such losses that the offense will not be able to win even by large-scale nuclear strikes against the defense. This is an important advantage of modern defense, the basis of which has to be a combination of holding firmly defensive areas which are separate, not clearly defined, but interrelated from the standpoint of firepower by decisive counterattacks from different directions by the reserves and the defending troops, carried out right after the delivery of nuclear strikes.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Proceeding from this, we consider it possible to indicate the fundamental directions in which, in our opinion, problems of modern defense must be solved.

1. Increase the firepower of the defense, the basis of which will be nuclear weapons and the firepower of antitank means; these means must permit the defense to win the battle of firepower against the offense and force the latter to give up the attack or delay it. The solution of this problem must follow the path of extensive shifts of trajectories of nuclear-missile weapons, as well as the path of creating in the defense, areas of resistance by fire, based on the utilization of systems of long-range control of antitank and rifle fire. The creation of areas of resistance by fire has very great significance in increasing the stability of the defense, as these areas are capable of resisting the nuclear strikes of the enemy much better than the conventional defensive areas can, and they can operate practically without limitations in an area that has been contaminated by radioactive materials.

2. Increasing the mobile capabilities of the defense and its aggressiveness, in order to stop an enemy drive by building up troops quickly in the threatened areas, and to destroy him by nuclear strikes, and bold counterattacks and counterblows. The solution of this problem must take the path of creating powerful mobile reserves dispersed along the front and in depth, and of developing new methods of conducting a defensive battle and operation, as well as the path of widespread use of portable obstacles, especially proximity-controlled minefields. A well thought-out system of quickly installed obstacles is capable of inducing confusion in the offense and inhibiting its progress at a point which is favorable for delivering nuclear strikes and executing counter-attacks.

3. Increase the capabilities of the defense for protection against the nuclear blows of the offense by means of a system of improving and developing new, high-efficiency engineer apparatus, of creating compact, portable designs of defensive installations that can be assembled and dismantled, of providing apparatus with hinges for entrenchment, of developing explosive devices for making individual foxholes and of carrying out other measures, directed at the fulfillment of tasks of engineer support of anti-atomic protection (PAZ) for several hours of units and large units, as well as the improvement of individual means of anti-chemical protection and of the protective qualities of combat equipment, directed

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

toward the assurance of the feasibility of conducting defensive operations in an area contaminated by radioactive materials.

The solution of these problems will be a qualitative advance in the organization and conduct of a defensive battle and operation, a new stage in the creative development of modern defense.

* * *

We have touched upon only a few questions of strategy and operational art, the correct interpretation of which, in our opinion, has profoundly important meaning for the solution of all other questions of military art. Not claiming that our judgements are infallible, we hope that a wide exchange of opinions in the pages of the special Collection regarding these questions will help to find their best solutions.

1. Headquarters Comment: According to [redacted], 1.3(a)(4) Col. Gen. Anton I. Gastilovich, who is on the faculty of the Military Academy of the General Staff of the Armed Forces of the USSR, wrote an article in the first issue of Spetsialnyy Sbornik Statey Zhurnala "Voyennaya Mysl" (Special Collection of the Journal Voyennaya Mysl). Conceivably such a collection was initiated in 1960, beginning with the 1960 First Edition.

COUNTRY : USSR

SUBJECT [redacted]limination of the Lag in Operational and Tactical Intelligence", by Lt. General M. Kochetkov

DATE OF INFO: 1960

APPRAISAL OF CONTENT : Documentary

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "Elimination of the Lag in Operational and Technical Intelligence", written by Lieutenant General Mikhail A. Kochetkov, who has long been associated with the Chief Intelligence Directorate (GRU), and in 1958 was Chief of its Operations (Transborder) Directorate (see also Headquarters Comment No. 2).

The article appeared in the 1960 Second Edition of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET and is issued irregularly. The month of publication of the 1960 Second Edition is unknown. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

Elimination of the Lag

in

Operational and Tactical Intelligence[1]

by

Lieutenant General M. Kochetkov

Vast changes in the nature of armed combat, caused by the appearance of weapons of mass destruction and, especially, of missiles of varying designation, necessitate the development of new intelligence (razvedyvatelnaya) techniques and their introduction into large units (soyedineniye) and groupings (obedineniye) of the branches of the armed forces and arms of troops, a re-examination of the organizational structure of operational and tactical intelligence from top to bottom, and the development of new forms and methods of combat activity of operational and tactical intelligence in peacetime and wartime. Naturally, the solving of all these questions must take into account the nature of a future war.

There is no need to prove the importance of operational and tactical intelligence. Its importance is adequately stated in the article of Marshal of the Soviet Union Comrade V. I. Chuykov in the first issue of the Special Collection of Articles of the Journal "Military Thought" (Voyennaya Mysl) for 1960. It would be useful to refer to the statement of the Minister of Defense, Marshal of the Soviet Union R. Ya. Malinovskiy, made by him at the 6 July 1956 critique. He pointed out: "Under modern conditions intelligence takes on extraordinary significance; it has never been as important as it is now and will be in the near future. It is impossible to count on victory if one does not have reliable information about the enemy. If we talk about operational intelligence - its importance is simply enormous. To know the plans of the enemy, the concentration of his forces, means, and formations (gruppirovka) and react to them accordingly - this is half the victory over the enemy."

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

It is known that the missile troops have moved up to assume first place among the other branches of the armed forces. There are missile troops of strategic designation which are the means of the Supreme High Command (VGK). On the successful operations of the latter depend the seizure of the strategic initiative in the initial period of a war and its retention during the war until the enemy is completely destroyed.

The missile troops of the VGK are capable of solving tasks at great strategic depth for eliminating from a war entire countries and other great strategic objectives, as well as destroying, in coordination with the ground forces, enemy targets in the theater of military operations (TVD) in the operational depth, beyond the range limits of the missile means of a front.

The operations of other branches of the armed forces - antiaircraft (PVO) troops of the country, the ground forces, the air forces (VVS) and the naval forces, are dependent on successful operations of the missile troops, which create conditions favorable for the operations of the others in the theater of military operations.

In examining the role and place of the branches of the armed forces in a future war, with the purpose of establishing their interrelationship and degree of independence, we come to the conclusion that even in peacetime the missile troops have to be provided with exhaustive, precise data on all objectives subject to destruction in the first counterblow of the missile troops against the aggressor. Naturally the missile troops must be targeted against these objectives in advance and be in a state of maximum readiness for an instantaneous counter-blow.

In connection with this, we feel that, on behalf of the missile troops of the VGK and fronts, an appropriate body composed of operatives (operator) and intelligence officers (razvedchik) should be created in the General Staff. Its task must include the collation of intelligence data on strategic and operational objectives of the countries of the imperialist camp, and the determination, depending on the importance of these objectives and their influence on the course of a war, of the order in which they will be subjected to nuclear strikes.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

This body should have an accurately worked out card index encompassing all strategic and operational objectives in both the strategic and the operational depth. The cards for each objective should specify: its characteristics, precise geodetic and topographic location (privyazka), the size of the nuclear charge, the type of burst (ground, air), the method of delivering the nuclear charge to the target, the amount of time needed to deliver the strike after the command is given, and other new data on the listed objectives, and reports on newly appeared objectives.

The first priority targets will be the individual, most aggressive, and dangerous countries, large political, economic, and administrative centers, military-industrial objectives, and mainly the depots with stockpiles of nuclear weapons, industry for the production of nuclear weapons delivery, air and naval bases, and the means of control and command of the missile troops and armed forces in the theaters of military operations.

Thus, it seems to us that only as a result of a successful, welltimed strike by the missile troops of the VGK can one count on an entree to the large-scale operational employment of all the other branches of the armed forces.

In peacetime conditions, strategic intelligence provides the VGK with the necessary intelligence data on the above-mentioned objectives. It should be pointed out, however, that these objectives are on the whole stationary, non-mobile, and, in place for a long time, which affords the opportunity for their exhaustive reconnaissance and study. Operational intelligence participates in these efforts to a limited extent.

As soon as the first atomic strike is inflicted and a war is unleashed, the situation, above all for intelligence, will undergo a tremendous change. The armed forces of the enemy will start moving, their large-scale movements will unfold, as well as dispersal to the theaters of military operations, and the nuclear-missile troops of the enemy, and other delivery vehicles of nuclear weapons, including aviation, aircraft carriers, and the missile-carrying fleet, will start maneuvering in the theaters of combat operations.

Under these circumstances new tasks will arise for intelligence, the significance of which is hard to overestimate.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

First of all, it will be necessary to clarify the results of our nuclear counterblow delivered by the missile troops, to continue intelligence operations against the nuclear weapons preserved by the enemy, the means of control and command, nuclear industry, the nature of the formations of the armed forces in the theaters of military operations and their plans and intentions. All new, mobile objectives must be discovered quickly by intelligence operations, so that a blow can be inflicted at once, and thus keep the strategic initiative in our hands.

In such a situation it is unlikely that we can count on the volume and timeliness of receipt of intelligence data as in the peacetime network, and it is all the more unlikely that it will be possible to avoid multistages in the levying of these tasks on the appropriate organs of intelligence. The time element will acquire extraordinary significance.

It appears to us that the missile troops of the VGK must now have their own means of long-range intelligence (manned and unmanned reconnaissance planes, radiotechnical reconnaissance, and other means) in order to carry out independent reconnaissance and re-reconnaissance of objectives, and react to any changes in the situation immediately.

Our armed forces, and mainly our missile troops, have first-class equipment, while operational and tactical intelligence and their technical equipment lag seriously. A certain gap between the means of destruction and the means of intelligence has developed.

Our intelligence does not have dependable technical means of detection of weapons of mass destruction. Reconnaissance planes are not yet able to find the launching pads of nuclear weapons and transmit the information acquired from aboard the aircraft directly to a control point. Aerial photography and the processing of photographs are done extremely slowly and are late in providing their results.

The technical means of radiotechnical reconnaissance also lag in their development. We still do not have dependable ultra-shortwave (UKV) hand direction finders, communications intercept equipment is poorly developed, troop reconnaissance still does not have television equipment, there are a few infrared

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

reconnaissance instruments, and photographic reconnaissance has not been perfected. The technical means of artillery and engineer reconnaissance have limited depth of operation, in that they can be used only in the tactical zone, which excludes the possibility of reconnaissance of the atomic means of divisions and corps of the potential enemies.

The time has come for a thorough investigation of the technical equipment of operational and tactical intelligence and to bring about the order needed. We consider that the serious fault which led to the lag in the technical equipment of operational and tactical intelligence is the absence of one central organ for operational and tactical intelligence in the General Staff which would occupy itself with questions of developing and providing technical equipment to intelligence units (chast) and subunits (podrazdeleniye) of all branches of the armed forces, just as it did at the end of the last war and during the period of existence of the reconnaissance corps (korpus razvedki). The Chief Intelligence Directorate does not deal with these matters at the present time, because it has been relieved of such work.

To the extent that their powers and capabilities permit, the staffs of the branches of the armed forces and their intelligence departments (otdel) are dealing with these matters. Therefore, it is not surprising that there is a lack of unity of views concerning the development and supply of intelligence equipment that in many cases there is parallelism and duplication, and that requirements of the General Staff and the Armed Forces as a whole for technical means of intelligence are not taken into account for appropriate orders to industry and planners. Every branch of the armed forces looks out for itself in the field of technical equipping of intelligence.

In order to close the gap between the means of destruction and the technical means of operational and tactical intelligence, it would be advisable to create an appropriate body in the structure of the Chief Intelligence Directorate capable of coordinating and planning the development of technical intelligence means on behalf of all the armed forces, working in close cooperation with the Scientific-Technical Committee of the General Staff and the Operational Directorate.[2]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The organizational structure of military intelligence from regiment through front needs serious re-examination.

The question of bringing order to the organizational structure and technical equipping of military intelligence, and increasing its penetrating capability, ties in directly with the decision of our government to reduce the Armed Forces without jeopardizing the overall security of the country. Obviously, the smaller the Armed Forces, the stronger and better organized must be the organs and means of intelligence, which is called upon to provide essential information to the VGK and to the command of all levels, both in peacetime and wartime.

It seems to us that the fundamental principle which should be used as the basis for the organizational structure of operational and tactical intelligence must be the creation of greater intelligence independence of divisions and armies from the higher staffs. The divisions and armies must provide themselves independently with the required intelligence information in the entire depth of an operation (battle), using their own means.

To be sure, in modern operations the army and division will be operating in much wider zones and at greater depth. Under the conditions of enemy employment of powerful nuclear and termo-nuclear (vodorodnyy) charges, divisions, with gaps of 20-40 km or more between them, whereupon large units that are moving ahead successfully are always obligated to be ready to assist a neighbor who has encountered a stronger enemy, which can cause a change in the direction of an offensive.

Besides, it is scarcely likely that, in the next war, one can expect to carry out classical offensive operations with break-throughs of a previously prepared defense or the conduct of defensive engagements under conditions similar to the previous ones. The meeting battle (engagement) will probably become the basic form of combat operation, and it will begin with the approach, and not upon direct contact with the enemy. Consequently, the intelligence operations of large units, using their own means, must ensure the collection, analysis, and collation of the intelligence data required by the commanders (komandir) of large units and the commanders (komanduyushchiy) of groupings in order for them to make decisions, with these units leaning primarily upon their own forces and means.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Thus, the intelligence forces and means of large units must provide intelligence to a depth on the order of 50-60 km, and groupings up to 300 km. In regard to a front, intelligence must embrace a depth of at least two front operations, so that at the end of the current operation, excluding any operational pauses, it would be ready to report full information about the enemy, his plans and intentions, for making a decision on the follow-up operation.

Along with the conduct of intelligence operations for themselves, the large units and operational groupings must perform a series of very important intelligence tasks on behalf of the higher staff, operational groupings, and the General Staff; in return, the General Staff and the staffs of the higher groupings, using their intelligence means, are obligated to service the lower intelligence organs and staffs.

Therefore, the next principle of organizational structure of operational and tactical intelligence must be the centralization of operational and tactical intelligence of the branches and arms of the armed forces, and the subordination of intelligence organs of lower combined-arms staffs to the higher ones, from the intelligence standpoint, with the General Staff playing the dominant role. In turn the intelligence organs of combined-arms staffs consolidate in themselves the intelligence operations of the arms of the armed forces.

The higher intelligence organs must direct, supervise, and assist their subordinates with the organization and conduct of intelligence operations, with the provision of intelligence equipment, with selection of personnel, and with the combat training of intelligence units and subunits, always maintaining the combat preparedness of the latter.

It is necessary to examine the questions of organizational structure along two lines: the structure of the intelligence organs proper, from the Center down to the regiment, and the structure of intelligence units, subunits, large units, and groupings subordinate to these organs.

The following structure of operational and tactical intelligence seems most expedient to us.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In the Chief Intelligence Directorate of the General Staff there should be a Directorate of Operational Intelligence. This directorate should be assigned the following tasks:

--Unifying the coordinating the intelligence operations of all branches and arms of troops;

--Planning and conducting intelligence activities of the intelligence departments of the branches and arms of troops on behalf of the large units and groupings of the branches and arms of troops and the General Staff (concentrating the intelligence efforts of the armed forces in a theater of military operations in the main directions);

--Working out the orders and directives of the Minister of Defense and the Chief of the General Staff concerning the status of operational and tactical intelligence, and the direction of its development;

--Guiding the intelligence work of the intelligence directorates of the staffs of military districts, especially the border districts, and the fleets, by all types and means of intelligence as a whole, not separating the latter for subordination according to the various echelons of command (air, agent, naval, radiotechnical);[3]

--Working out, for design bureaus and scientific-research institutes, the tactical-technical data of the technical means of intelligence for all branches of the armed forces in order to eliminate duplication and parallelism in the work, coordinating this work with the intelligence departments of the branches of the armed forces;

--Publishing bulletins about current questions of operational and tactical intelligence of the branches of the armed forces, and also manuals and instructions on operational and tactical intelligence;

--Direct participation of the Directorate in working out large exercises and maneuvers carried out by the Ministry of Defense, the General Staff, and the staffs of the branches of the armed forces, in order to accumulate experience in intelligence, and to study and work out questions in its planning and conduct, collect intelligence data for use by the troops, and also to develop informational work in all elements of the intelligence organs;

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

--Participating in tests of appropriate intelligence and special equipment;

--Carrying out experimental and demonstration exercises in intelligence;

--Participating in the instruction, posting, and training of intelligence personnel from divisions of all branches of the armed forces up to chiefs of intelligence directorates of military districts (fronts); and other questions.

It is known that operational intelligence was not prepared at the beginning of the last war. Therefore, while the war was in progress, a search was made for organizational forms and working methods, and not until 1943, 23 months after the start of the war, did operational intelligence acquire an acceptable organizational structure in troop units and in the General Staff, in which was created the Reconnaissance Directorate.[4]

Under modern conditions we consider it impractical to create such an independent directorate, but it is quite necessary in the structure of the Chief Intelligence Directorate (GRU) of the General Staff. It is unlikely that, in the next war, we shall have as long (23 months) for working out the structure of operational intelligence as a whole, and in the General Staff in particular, and for the accumulation of experience in the combat activity of operational intelligence. All this work should be carried out long before the war. The lessons of history must be taken into consideration. In the postwar period, when the reconnaissance corps was in existence, there was such a directorate in the GRU of the General Staff and it did a lot of work, but then, instead of developing it and improving operational intelligence, it began to lose its importance and then ceased to exist. This deficiency should be eliminated quickly. This will not require a large number of personnel.

It is advisable to enlarge somewhat the intelligence departments of the branches of the armed forces. These departments must fully guide the operational and tactical intelligence of their branch of the armed forces and organize and carry out combat training of intelligence subunits and units, in accordance with the orders and directives of the Minister of Defense and the Chief of the General Staff, with the coordination and guiding role in this

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

work performed by the GRU of the General Staff.

It is necessary to restore to duty the chiefs of intelligence of the arms of troops, providing them with a small organization, 2 or 3 persons, and giving them the responsibility for carrying out the guidance of intelligence in their arm of troops.

It is necessary to examine the intelligence directorates of military districts and fleets, and bring them into line with modern requirements, taking into account the fact that in the first operations of the initial period of a war, the border military districts will have to operate with the forces and means on hand. Therefore, it is advisable for the intelligence organs, units, and sub-units of these military districts to be close to the wartime table of organization and equipment even in peacetime.

It is advisable to strengthen the intelligence departments of armies so that they can fulfill the tasks facing them. It is necessary to do the same regarding the intelligence sections (otdeleniye) of divisions (large units).

It is absolutely necessary to raise the authority of intelligence and the chiefs of intelligence at all levels, in fact, not just paying the latter lip service as deputies to the chiefs of staff, and to relate them more closely to the chiefs of the operational sections, departments, and directorates, and demand that they perform creative and active work. In regard to the structure of units and subunits of intelligence, supplying them with intelligence equipment, as well as the question of what means, units, and subunits the large units and groupings of the ground forces should have at their disposal, we have at this time nothing to add to that which is stated in the article of Marshal of the Soviet Union Comrade V. I. Chuykov. The implementation of his proposals will permit a sharp improvement of operational and tactical intelligence.

We have touched upon only a few of the important questions. Obviously, in the future it will be necessary to discuss these problems of operational and tactical intelligence more fully in the pages of this Collection.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Headquarters Comments:

1. According to other reliable sources, the GRU is charged with the collection of strategic intelligence (strategicheskaya razvedka), so-called operational intelligence (operativnaya razvedka, information bearing on opposing armed forces in one theater of operations), and so-called military intelligence (voyskovaya razvedka, information supporting unit commanders in the furtherance of immediate, localized combat missions). Apparently the term tactical intelligence (takticheskaya razvedka) has supplanted the term military intelligence.

2. This is the Operational Directorate of the General Staff, concerned with military operations, and should not be confused with the now-defunct Operations Directorate of the GRU. Many of the functions proposed by Kochetkov for the "Operational Intelligence Directorate" (see page 9, first paragraph) were formerly performed by the GRU Operations Directorate.

3. The responsibilities for both agent operations and radio-technical (communications and electronics intelligence) activities are known to have been held by the Intelligence Directorate of the Group of Soviet Forces, Germany (GSFG) as of 1958.

4. This term (Razvedyvaltelnoye upravleniye) can also be translated as Intelligence Directorate, but from the context Reconnaissance Directorate appears more accurate. It is not clear how the GRU is able to distinguish between the two designative concepts, intelligence and reconnaissance.

MEMORANDUM FOR THE RECORD :

SUBJECT : Conversation with Mr. Helms Re [redacted] Report on Large-Scale Soviet Military Preparations 1.3(a)(4)

1. When Mr. Osborn and I were discussing the above report with Mr. Helms, upon its receipt yesterday afternoon, I told Mr. Helms we should expect renewed consumer questions about the possibility of deception. I pointed out that the [redacted] material had not only been accepted by most of our consumers, but that the material was: a) extremely costly in terms of Soviet security; and b) apparently inconsistent with any discernible Soviet policy purposes. However, I said we must face up to the fact that [redacted] was now in a key positionto give us information vitally affecting our own reaction to recent Soviet moves. For example, [redacted] could assure us that all the preparations we would be seeing over the next few weeks were, indeed, part of the maneuvers already described, in which case the Soviets would beable to take aggressive military action without alerting our indications mechanism. On the other hand, at some critical juncture, [redacted] might tell us that the Soviets were now ready to strike unless we made significant concessions, even though, in fact, the entire Soviet effort was bluff. 1.3(a)(4)

2. Mr. Helms agreed that such questions would probably arise, but that we should take the position that the consumers themselves would have to make up their minds as to the answer. He said all we could vouch for was that, from strictly an operational standpoint, we had been unable to fault [redacted] and could see nothing in the operational and CE aspects of the case which would cause us to question the validity of the information being supplied. 1.3(a)(4)

COUNTRY : USSR

SUBJECT : [redacted] The Paths of Further Development of the Tank Troops of the Soviet Army", by Marshal of Armored Troops P. Rotmistrov

DATE OF INFO: Early 1961

APPRAISAL OF CONTENT : Documentary

SOURCE: Reliable Soviet source (B) who has access to this type of document.

Following is a verbatim translation of an article entitled "The Paths of Further Development of the Tank Troops of the Soviet Army", written by Marshal of Armored Troops Pavel A. Rotmistrov, Chief of the Military Academy of Armored Troops i/n Stalin.

The article appeared in the 1961 First Edition of The Special Collection of Articles of the Journal "Voyennaya Mysl" (Military Thought), instituted in 1960, which is classified TOP SECRET and is published irregularly. According to the preface, this edition contains articles never before published and some speeches which have been delivered prior to being published in this form. It is distributed only within the Ministry of Defense down to the level of Army Commander.

Many points in Rotmistrov's article are challenged in an article by General of the Army A. S. Zhadov in the 1961 Second Edition of this Special Collection. (Cf. [redacted] dated 12 September 1961.) 1.3(a)(4)

The Paths of Further Development of the

Tank Troops of the Soviet Army

by

Marshal of Armored Troops P. Rotmistrov

There have been pronouncements of late on many questions connected with the development of tank technology and the organization of tank troops. One can hear the opinion that it is pointless to have strong armor plating on tanks in view of the appearance of new, highly effective antitank means (above all of guided antitank missiles - snaryad), and also because of difficulties related to the production and use of heavy, tracked combat vehicles.

In connection with the probable re-arming of tanks with guided missiles (upravlyayemyy reaktivnyy snaryad) instead of tube artillery armament, it is also said that it is necessary to re-examine the design of tanks. In particular, proposals are advanced that the production of heavy tanks and the development of prototypes be stopped. In this case there will be only two types of tanks with which our tank troops can be equipped: medium (the basic type) and light (amphibious), instead of the three that now exist.

It is impossible not to admit that the pronouncements and proposals cited touch upon fundamental questions of the further development of armored technology, organizational structure, and of the combat use of tank troops.

A proposal that is no less important, which is also widely discussed and which has its supporters, is the elimination of tank armies and divisions and conversion to mixed organization of an army and a unified division.

We do not share the views of the "innovators", since they are not scientifically founded and are not supported by the experience of the last war. Inasmuch as there are no official decisions concerning these questions as yet, we shall permit ourselves to express our viewpoint.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Conditions that determine the directions of the further development of tanks. A tank is a tracked combat vehicle of high cross-country ability incorporating three basic combat qualities: firepower, armor protection, and mobility. During the existence of the tank these qualities have constantly been improved as regards achievements in the development of armament, armor protection, power transmission, and running gear, as well as by changes in operational-tactical views on the employment of tank troops.

The choice of the directions of development of the basic combat qualities of our modern tanks was made on the basis of the experience of the last war. During recent years further development has been mainly concerned with increasing the accuracy of fire when in motion (stabilizers), of broadening the scope of combat utilization (firing at night and under conditions of poor visibility, the surmounting of water obstacles by floating or by moving along the bottom of the water), and of increasing the reliability of operation of separate assemblies and of the vehicle as a whole.

The correct determination of basic combat characteristics ensured the superiority of our tanks over the comparable types of tanks of the capitalist countries during the last war and in the postwar period.

At the present time the development of new types of weapons, and above all of the means of mass destruction, makes it necessary to determine the paths for the further improvement of the combat qualities of tanks which are applicable to the newly arising conditions of a possible war.

The present period of tank development is characterized by the fact that the decisive factor for further improvement is not so much past combat experience, with all its value, but a scientific forecast of the nature of a future war, the role of tank troops in it, and the methods of their combat employment. In other words, the basic trends in the development of armor technology should be determined now, above all, by the presence of nuclear weapons and missile capabilities, and by the development of tank technology and of the means of defense against tanks.

Proceeding from a thorough analysis of the nature of a future war, it must be considered that the decisive force in the ground troops will be tank troops, in cooperation with

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

missile troops and aviation. The basic assignment of tanks in modern combat operations will obviously be: combat with the tanks of the enemy, destruction of missile launchers on the launch sites, suppression and destruction of the various other firing means, the means of control, reconnaissance, and supply, as well as the personnel of the enemy, including those in armored carriers and in shelters. Proceeding from this, it is essential to lay special stress on the multi-purpose assignments of tanks and their armament not only at the present stage, but also in the near future. From the conditions of highly mobile troop operations and of great independence in the employment of tank units (chast), sub-units (podrazdeleniye), and individual tanks, dictated by the use of weapons of mass destruction in a battle and an engagement, arises the need to include in the armament of our troops tanks with high resistance to all the destructive (porazhayushchiy) factors of a nuclear explosion, with great cruising range, and which are also powerfully armed and carrying a significant supply of ammunition for various missions, above all of shells (snaryad) effective against the tanks of the enemy.

The armor protection of tanks. As was mentioned before, one hears nowadays the opinion that, owing to the appearance of new antitank combat weapons, there is no longer a requirement for tanks with thick armor. Among others, a proponent of this viewpoint is Colonel-General A. I. Gastilovich, who writes literally in his article ("The Theory of Military Art Requires Review", Spetsialnyy sbornik statey zhurnala Voyennaya Mysl, First Issue, 1960.) that the ground troops as a whole should be made air-transportable with lightly armored (oblegchennyy) tanks, as any armor can be penetrated anyway.

In this article we do not have the opportunity to examine other questions raised by General Gastilovich. At the same time, it is impossible to bypass the question cited without drawing the attention of the author to the fact that not only are light tanks incapable of engaging independently in battles with tanks of the enemy (General Gastilovich, it should be said, calls upon our tank divisions to do this, on page 13 of the Special Collection), but they will also suffer heavy losses from nuclear strikes by the enemy, and thus our tanks and tank troops as a whole will only lose by these "innovations". Consequently, it is impossible to reject, so rashly, reliable armor protection of modern tanks.

The complexity of creating proper armor protection for tanks under modern conditions, in relation to the development of powerful means of destruction, is further conditioned by the fact that this

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

protection must be over-all, i.e., that it is called upon to protect personnel against destruction by various types of weapons that operate on different principles.

Thus, the armor-piercing shell with high muzzle velocity which is used against tanks presents one requirement to the armor material.

Nuclear weapons have introduced other requirements, namely, the need to protect tanks against the shock wave of a nuclear explosion and against penetrating radiation (gamma rays and neutron flux).

In this connection, it must be kept in mind that while steel armor offers good protection against the shock wave of a nuclear explosion (here we take into consideration the strength of the hull and turret) and successfully resists gamma-radiation, which is connected with the heavy specific gravity of steel, it affords slight resistance to the flow of fast neutrons. In regard to radiation of light waves it should be said that the existing armor of tanks eliminates this danger to the crew.

Finally, the use of shaped-charge (kumulyativnyy) shells, as is known, is based upon a different principle of destruction, which is most effective against steel armor. We recall that the first attempts to use shaped charges in combat occurred during the period of the Spanish Civil War (1936). During World War II shaped-charge antitank means were greatly improved (panzerfaust, bazooka, and others) and were quite widely used.

In the postwar period the sphere of employment of shaped charges as a means of combating tanks has widened even more; this is evidenced by the further improvement of shaped-charge shells in conventional tube artillery, the creation of recoilless weapons with shaped-charge shells, and, finally, the appearance of guided missiles with shaped charges.

The highly effective action of shaped charges against steel armor, the widespread possibilities of their use, and also the appearance during the last few years, in many countries, for example, France, England, the USA, West Germany and Switzerland, of various models of antitank guided missiles (PTURS) (See Table 1), have introduced the problem of providing protection for tanks from destruction by shaped charges, which should be gone into in more detail.

Some foreign military experts think that the appearance of PTURS with shaped charges opens a new era in combat with tanks and leads to a fundamental change in the equipment (tekhnika) and tactics of armored troops.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

With all the diversity of known PTURS, they can be differentiated basically by the type of rocket engine (solid - porokhovoy - or liquid) and by the system of guidance (navedeniye) to the target. Guidance (upravleniye) is by wire, radio, or by means of an infrared homing head.

The firing of antitank guided missiles is done from ground launching mounts (puskovaya ustanovka) installed on vehicles, armored carriers, and other mobile means.

In comparison with other antitank means, these missiles have a number of advantages. They are easy to handle and, being guided in trajectory, display great accuracy in tests. Unlike conventional antitank weapons, the operator does not have to determine distance to the target and its rate of movement when firing a guided missile. And finally, the main thing, which allowed some experts to speak of the onset of a new era in combat against tanks, is the great depth of penetration of steel armor, equal to 400-450 mm or more for a normal hit.

These positive qualities of antitank guided missiles predetermine their widespread use in battle. But one must not go to extremes and draw hasty conclusions, which often happens when technical achievements are evaluated from only one standpoint.

Our creation of antitank guided missiles, of which the tactical-technical characteristics are on a level with foreign models, apparently served as one of the main grounds for the pronouncements on the inexpediency of using heavy armor on tanks, inasmuch as it is allegedly practically impossible to install armor protection of tanks that could withstand the modern means for their destruction.

The mistake in such reasoning lies in its one-sidedness, and arises from an inadequate appraisal of many factors connected with the conditions of employment of these means, and also from forgetting the powerful combat characteristics of tanks.

The launching mounts of antitank guided missiles are basically a means of defense; they cannot be used in a tank meeting engagement and have absolutely no protection from the effects of nuclear weapons, which seriously limits the possibilities for their combat employment. Even in the defense these launching mounts are easily destroyed by tactical nuclear weapons. Besides, they will be unable to move over contaminated terrain right after a nuclear explosion, while tanks will operate without delay, exploiting the success after the use of a nuclear weapon against the enemy.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Data on the great firing accuracy of PTURS were obtained under firing range conditions, in other words, without interference by the enemy.

The receiving apparatus of an antitank guided missile is highly sensitive to the signals of the operator. It is enough to force the operator, who works under conditions of direct contact with the enemy, to commit any unintentional movement of the binocular sight (visor) at the instant the missile is being laid on, even to start at the explosion of a hostile shell, and the PTURS will change its flight course and miss the target.

PTURS mobile launching mounts on light transport equipment can be suppressed effectively by modern means of mass destruction.

Besides this, the known models of antitank guided missiles have the following substantial faults:

- during the intitial stage of flight, for a sizeable part of the trajectory (up to 500 meters), they are still unguided, i. e., they have a sizeable "dead" (mertvaya) zone in which they present no danger to tanks; for the same reason they are of little use for combat operations under city conditions;

- when firing from launching mounts, located on the ground, or on vehicles, they have a limited shift of fire;

- with instantaneous-action fuses, if the missiles meet even the slightest resistance in their trajectory (bushes, fences, etc.) they may explode before reaching the target;

- they have a low velocity, so that it takes 15-30 seconds for them to travel 2-3 km; during this time the enemy can destroy the operator or his guidance instruments with counterfire, after which the missile becomes unguided.

For wire, radio, and infrared ray guidance it is necessary for the operator to see the target during the entire flight time of the missile in order to keep the missile on the line of sighting. As a rule, in cases when the target is lost for a few seconds, the missile will also be lost.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Firing by tanks at guided missile launching mounts, the laying of smoke screens, and also the utilization by tanks of folds in the ground, features and structures, trees, and bushes when approaching the enemy will lead to a considerable reduction in the effectiveness of guided missiles used against tanks.

The analysis of the qualities, possibilities, and conditions of combat use of recently developed models of antitank guided missiles with shaped charges, possessing high armor-piercing capability, allows us to state with full responsibility that their appearance in the presence of means of mass destruction and tanks does not give us sufficient basis to conclude that it is inexpedient to use a strong armor protection on the basic types of Soviet tanks. Besides, it should not be forgotten that a tank with strong armor, moving rapidly over the battlefield and firing simultaneously, has always had superiority over antitank weapons. Of course, it is necessary to consider the possibility that the antitank weapons mentioned may be improved or that new, more effective ones will appear. However, tanks will not remain at their present stage of development either.

In examining the question of the necessary armor protection of the basic types of tanks, we consider that it must be over-all, i.e., capable of giving the tank great resistance, protecting the crew from weapons of mass destruction and enemy tanks, and also from various modern antitank weapons.

Therefore, we must not slacken our efforts to perfect the strong armor protection of the basic types of tanks, which must be strengthened supplementarily for the biological protection of the tank crew from penetrating radiation by the use of special "linings" (podboy) which inhibit the flow of neutrons. But, again, it must be remembered that the "lining" will be of use only in conjunction with dependable armor.

Improvement of the armor protection of tanks from all types of shaped-charge weapons (and not only from PTURS) must be carried out by using large angles of inclination of the armor details, the differential distribution of armor in relation to the probability of damage to the tank on the battlefield, the use of shields of various designs to induce activation of the fuse of the missile before it reaches the main armor, and, finally, by creating a combined armor consisting of armor steel and glass plastic (stekloplastik) which resists the shaped-charge effect well.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Nor should it be forgotten that the presence of weaker armor protection on tanks on one belligerent side puts the tank troops of that side at a disadvantage in advance, especially in carrying out a meeting battle and engagement. But this type of combat action will be basic, as we know, especially in the initial period of a war.

As regards the position taken on the need to increase the armor protection of the basic types of tanks, one must not conclude that it is inevitable that their weight will be increased thereby. Even now we should strive to reduce the weight of tracked combat vehicles, but not at the expense of their combat qualities, because weight still adds to their great resistance to a nuclear explosion, which leads to the broadening of the sphere of their combat utilization.

When we speak of resistance, we mean not only resistance to overturning, but also the ability to withstand all the other factors of a nuclear explosion.

The possibility of increasing the armor and still retaining the same weight of a tank can be illustrated by an example of Soviet tank construction.

Thus, the T-34 tank, which was the best tank of its day, has been replaced by the T-55 medium tank, which has armor and armament more than twice as powerful, with only a 12 percent increase in the weight of the vehicle.

Even now there are certain opportunities to increase further the combat qualities of tanks under conditions of their use in a war employing nuclear weapons without increasing their weight. At the same time, however we strive to reduce the weight of tanks, we should not do so under any circumstances at the cost of weakening the hull of a tank.

The heavy tank: Up to the present some comrades have expressed the thought that it is pointless to produce heavy tanks. We hold a different opinion indeed.

First of all it should be noted that the concept of a "heavy tank" is quite relative. Our T-10 and T-10M tanks with a weight of 50 tons are called heavy, while the American tank M60 that weighs 47 tons is medium. The British 50-ton "Centurion" tanks are also considered medium. The latest models of American and British heavy

[redacted] 1.3(a)(

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

tanks weigh 57 tons and 65 tons, respectively, and the well-known heavy "Tiger-B" tank of the former German-Fascist army weighed 68 tons.

Therefore, it seems to us that it is not a question of the name, but of whether we need a type of combat vehicle such as our T-10M tank, or not?

When this question is examined it is helpful to recall the relationship between our tank types during the last war. Statistics show that during World War II we had about 55 percent medium tanks and assault guns (SAU), up to 25 percent light tanks and SAU, and about 20 percent heavy tanks and SAU. Of course, such a high percentage of light tanks existed because of the well-known conditions, and, in particular, because it was possible to build them in ordinary automobile plants.

So far as the production of heavy tanks is concerned, they were produced only out of necessity, because of the harsh demands of war. They were produced despite all wartime difficulties and, as the experience of the last war showed, their production was fully justified.

In our opinion, it is impossible to go only on economic considerations in evaluating the significance of heavy tanks under the new conditions. It is really hard to produce heavy tanks; they require a lot of metal, but for defeating an enemy one cannot skimp with metal. Apparently, in this case, when examining the question of heavy tank production, it is necessary to approach it not only, and not mainly, from a purely economic standpoint, but above all by evaluating military necessity and expediency.

Let us note here that at the present time the percentile relationship of heavy tanks to medium ones (if we consider only the T-10 and T-10M tanks) is in all only about 4 percent. In other words, we actually have only one type of tracked combat vehicle, since the light, reconnaissance amphibious tank is not suitable, it seems to us, for conducting tank battles, and in reality we have so few heavy tanks that any restrictions on their production will reduce their significance in our troops to zero.

The question arises: Do we actually have to limit ourselves to one type of tank and to consider this a normal phenomenon in the development of armored technology?

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In our opinion, this must not be done, not only from considerations of ensuring qualitative superiority over the enemy, but also on the grounds that it is essential to broaden the development of designs of tracked combat vehicles.

It is known that the U.S. Army, our probable enemy, has accepted the M60 tank into its armament, and it not only concedes nothing to our medium tank in most respects, but is even superior to the latter in some. For example, the armor protection of the frontal (lobovaya) armor of our T-55 tank hull is 100 mm, and of the American M60 tank, 120 mm. Our tank is armed with a 100 mm gun, and theirs with a 105-mm gun. The muzzle velocity of an armor-piercing shell from our gun is 900 m/sec, and from theirs - 975 m/sec. Our unit of fire is 43 rounds, and theirs - 57. The engine power of the T-55 tank is 580 h.p., and the M60 - 750 h.p. The capacity of our main fuel tanks is 680 liters, and theirs - 1,300 liters.

Our T-55 tank has an advantage over the M60 tank, for example, in the dimensions and weight of the vehicle. This, however, does not give us the right to disregard the definite progress attained by the USA in the construction of medium tanks.

At the same time our T-10M heavy tank is superior to the latest models of foreign medium tanks, including the M60, in a number of basic combat features, especially in firepower and armor, and is equal to them in maneuverability.

Consequently, if we reject the T-10M tank at the present time it can lead to the loss of our qualitative superiority over the tanks of the enemy. Therefore, we should not reject heavy tanks at the present time, particularly the T-10M tank, but on the contrary, it is necessary to arrive at a decision that would again ensure our superiority over the tank technology of the enemy, especially in tank battles and engagements.

It follows that an incorrect selection of the necessary types of tanks will do serious damage to the army. This problem assumes special significance at certain stages in the development of tanks, as the result of general technical progress and the appearance of new methods of conducting combat operations.

CONSIDER

We consider that the main purpose and meaning of the existence of heavy tanks in our army consists of the fact that, having stronger combat characteristics than medium tanks, especially in

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

firepower and armor protection, they ensure our qualitative superiority over the tanks of the enemy, which is impossible to achieve with medium tanks alone.

The M60 tank that the U.S. Army has adopted is called the "basic combat tank". At the same time, despite its extremely powerful armament and armor, the Americans, as a reinforcing measure, have created numerous tracked assault guns of large calibers (from 155 to 240 mm), with armor giving full protection from bullets and with a special system of anti-atomic defense.

The armament of the newest models of these assault guns is installed in revolving turrets: it has mechanized loading and a fairly large unit of fire. Some of them are so adapted that they can cross water obstacles afloat.

Consequently the American "basic combat tanks" have various and powerful means of reinforcement which have great mobility and cross-country ability, adapted for crossing terrain that is contaminated with radioactive substances. However, the weak armor of the assault guns limits their use in certain types of combat.

Under prevailing conditions our basic (medium) tanks also need means of reinforcement that would be capable of destroying the enemy's tanks at great distances, firing by direct laying and without reducing the maneuverability of the tank troops.

These methods for the qualitative reinforcement of medium tanks can be:

- heavy tanks, greatly superior to medium tanks in firepower and armor;
- assault guns, created both on special chassis and on the chassis of a medium tank, which would have more powerful armament than the latter.

The first way is preferable. The presence of strong armor protection on the heavy tanks increases the possibilities for their combat utilization, compared to the SAU mounted on the chassis of medium tanks, not to mention the assault guns with only bullet-proof armor, especially in a meeting engagement.

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Besides, if the final design of a heavy tank exists, new combat vehicles for various purposes can be created on this basis in a relatively short time if the need arises (missile carriers, powerful assault guns, including those using nuclear weapons and others).

Thus, bearing in mind that the enemy has the 47-ton M60 tank and various reinforcing means, we come to the conclusion that in order to ensure superiority over the tanks of the enemy and to strengthen our medium tanks qualitatively, it is necessary for us to have heavy tanks or some other vehicles which have firepower superior to that of the basic tank of the enemy.

The aspiration to reject heavy tanks and to reduce the weight of tanks by reducing the thickness of the armor, will lead inevitably to a sharp decrease in the combat capabilities of tanks and will place our tank personnel in an unequal position in the conduct of a battle with the tanks of the enemy. As has already been pointed out, the weakening of tank armor does not conform with the requirements for anti-atomic protection.

In consequence, if we examine the heavy tank question scientifically, it is essential to study many conditions. Therefore, the decision which is adopted has to be deeply founded to eliminate any possibility of making a mistake in this important question.

Some questions of the organization of tank troops: Lately, as we have already mentioned, there have been statements on the necessity of reviewing the organizational structure of the tank troops. More than that, there are even suggestions that we should reject the concept of "tank troops".

The supporters of the views indicated consider that the mechanization of modern ground troops and their saturation with tanks has somehow led to the fact that there is little difference in the ground troops between motorized rifle divisions and tank divisions, with the result that tank troops nowadays lose their independent significance. For this reason there are proposals to abolish tank divisions, tank armies and the concept of "tank formations".

In stating the concept of creating unified divisions as the basic tactical large unit (soyedineniye) of the ground troops, its proponents have foremost in mind the rejection of tank divisions.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In examining this question the experience of the last war and the economy of the country must be taken into consideration. It appears to us that unified divisions, saturated with tanks, will not be needed everywhere. In many cases, in some theaters of military operations, and in many areas of the West European theater, it will also be possible to have standard motorized rifle divisions with a limited number of tanks, or even without them. If all the divisions are thoroughly saturated with tanks, the economy of the country will be unable to support such a huge tank park. Moreover, the opportunity to mass tanks where it is deemed to be operationally expedient always remains, without their organizational disintegration.

These concepts oblige us to have at least two types of divisions.

It is well known that nuclear weapons have brought about many corrections, not only in combat tactics, but also in military art as a whole. Under conditions of the use of weapons of mass destruction, war will be more mobile with higher rates of advance than formerly, and operations will attain a large scale. All this will call for more frequent and more intensive troop movements than before.

Proceeding from this, some comrades consider that tank divisions do not fully meet specified requirements, and that they are inferior to the motorized rifle divisions in mobility except on the battlefield. In particular, they assert that the motorized rifle division is superior to the tank division on the march, because it is necessary to have strong bridges, heavy ferries, and pontoon bridges for tanks to cross a water barrier, and tanks are supposedly slower than wheeled vehicles and armored carriers, etc. Therefore, in their opinion, all the advantages remain with the motorized rifle division, in a given case.

It is entirely obvious that none of these conclusions is sound. On the march the motorized rifle division has no advantages, and cannot have any, over the tank division, because it has tanks of its own and moves at the speed of the tanks. Because of the presence of tanks in the motorized rifle division it needs bridges just like the tank division, so even in this sphere the motorized rifle division has no advantages of any kind.

Indeed, in battle, as soon as the motorized infantry (motopekhota) leaves the armored carriers, the motorized rifle division will be forced to advance at the speed of infantry (this will sharply curtail its maneuverability and rate of advance), while tank units and sub-units

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

will have to operate without infantry, because on the battlefield it is impossible to combine the speed of tanks -- 20 km/hr -- with the speed of infantry -- 4 km/hr -- and the power of a protected engine -- 500 hp -- with the strength of a man without any protection.

All combat experience of World War II points to the fact that it was not rifle divisions reinforced with tanks that determined the success of operations, as, for example, French military theoreticians believed, but tank divisions, tank corps, and tank armies.

All those who maintain that the organization of a unified division is more progressive than the organization of our tank divisions, are, in our opinion, bearers of old-fashioned ideas.

The tank division fully justified itself in the last war, and it will justify itself even more under the conditions of a war conducted with the use of nuclear weapons. In examining current problems, one should proceed first of all from the effects of the employment of nuclear weapons. This must be taken as the basis of the organization of the troops. If this is so, and if it seems that no one takes issue with this thesis, then we have to create an organization that will meet all the modern requirements.

Upon thorough examination of this question, one may assert that the inadequacy of the proposed organization of a unified division will be proven by every nuclear explosion. A nuclear explosion will put everything that is on the battlefield out of commission, except the tank crews, who are covered by thick armor. It might be asked, why build illusions and create an organization of troops that is known beforehand not to meet the requirements of modern warfare?

More than once, the Minister of Defense, Marshal of the Soviet Union R. Ya. Malinovskiy, pointed out that in the next war, as never before, there will be an increase in the number of tank meeting engagements and battles. He did not forget to remind us of this during this year's critique of exercises, by pointing out that "meeting battles and engagements will be the most common phenomenon". This is understandable. These battles and engagements will have to be carried out, above all, by our tank troops against the tank troops of the enemy; this is borne out by the fact that they are best adapted for the conduct of battles under nuclear warfare conditions, and that they can engage, most successfully, the enemy tanks. This thesis is upheld by the entire course of World War II, and especially during the engagement at Prokhorovka on 12 July 1943.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

During this meeting engagement the blows of the German tank troops were sustained only by our tank troops. It is a fact that the fresh, battle-tested 5th Guards Combined Arms Army under the command of such an experienced warrior as Lieutenant General A. S.Zhadov, not only did not fulfill the order of the Commander of the Voronezh Front, General of the Army N. F. Vatutin, and member of the Military Council N. S. Khrushchev to carry out a joint counter attack with the 5th Guards Tank Army, but did not even hold the lines being occupied. Its corps on the left flank, unable to sustain the onslaught of the German tanks, withdrew quite a distance to the east, and exposed the right flank of the 5th Guards Tank Army, which was already in a difficult situation without this. Despite the conditions that arose, the 5th Guards Tank Army not only closed the right flank with its own tank units, but also detached one brigade to the assistance of the 5th Guards Combined Arms Army. How can we forget these lessons of history now, and propose without foundation or due analysis a new universal division whose combat value appears highly dubious, and reject the tank division which proved itself throughout all of World War II and has not compromised itself yet?

It is perfectly apparent that the conversion to a universal division will lead to the rejection, not only of the tank division, but also of the tank army, and this will lead inevitably to the extensive dispersal of tanks and to the loss of all the advantages which they possess when they are organizationally massed.

In this respect, we consider it quite proper that a lot of attention is directed to the question of a new organization of the troops.

In modern conditions military art does not at all presuppose a universal organization of the basic large units of the ground troops, for it would be hard to combine the combat qualities of the various new types of weapons and combat equipment. On the contrary, it is necessary to create an organizational structure which will provide the most effective ulitization of combat equipment.

Thus, it seems advisable to us to have not one universal type of division, but three types of divisions:

First - a tank division to conduct combat operations under conditions when nuclear weapons are used, to conduct meeting battles with enemy tanks, and as the basic means for carrying out deep strikes on the offensive and repelling enemy strikes on the defensive. Its

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

organizational development must tend toward the further reduction of personnel not protected by armor and saturation with heavily armored tanks.

Second - a motorized rifle division which should be more or less the same as it is now, maybe even with some reduction in the number of tanks, or else in wartime we may not be able to maintain all motorized rifle divisions at TOE strength in tanks. Besides its general missions that were pointed out in the order of the Minister of Defense for 1961, it can be used to secure general success in the main direction, for performing basic missions in minor directions, and for effecting a firm defense.

Third - a light motorized rifle division without tanks. In our opinion, a division of this type could carry out fast marches in armored carriers over light bridges and crossings, cross contaminated zones without engagement, move by air into the enemy rear or into an area of our strong tank formations to consolidate their successes, conduct stubborn defense of terrain that tanks cannot reach easily, etc. If a division of this type is armed with modern antitank weapons, under favorable conditions it will be able to hold an area or line securely and repel enemy tank attacks. In cases when a division of this type is thrown into an area where we have strong tank formations it can be reinforced with tanks if the necessity arises.

It seems to us that the presence of three types of divisions in the organization of the ground troops will fulfill the requirements presented by modern warfare better than one unified division.

The pronouncements of some of our military leaders that the tank army has outlived itself, and that the time has come to shift to an army of unified organization, are not new. Such conclusions are a direct consequence of the rejection of the tank division and the creation of a single, unified division.

In this connection, it is pertinent to remember that in the history of the development of armored troops there was a sad day when the tank and mechanized corps found themselves disbanded. Everyone knows what consequences this led to.

At the root of such views on the modern tank army is the assertion that it does not differ in any way now from the combined arms army, that in operations, exercise experience shows, it cannot break away from the other forces of a front, and its existence is, therefore,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

supposedly not justified in any way.

Such pronouncements are, to say the least, unfounded. The experience of World War II testifies to the fact that all of the most successful operations, not only offensive but also defensive, were won by our troops largely with the participation of tank armies. Tank armies provided the front with wide mobility, power, and depth of strike, developing operations at high tempo.

It is permissible to pose this question to all comrades who espouse the concept of abolishing tank armies: Do they now reject the concept of massed strikes, or is this method of defeating the enemy also obsolete?

If we consider that even now, in the age of nuclear weapons, it is necessary to fight with the fist, then how can we come out against the tank army if its organization already incorporates the principle of massing tanks. We do not wish to go into this question further and introduce other arguments of the superiority of the tank army over the combined arms army in offensive operations, but it seems to us that, to any person capable of objective evaluation, it must be clear that if tank armies played a leading role in the success of operations carried out during the last war, then their role in a future war, more mobile than the last, will increase more and more. The tank army was and will remain the most menacing force to the enemy, especially in a meeting engagement against his tank formations.

The experience of World War II teaches that the utilization of tank troops differed, and will continue to differ, from the use of rifle troops reinforced with tanks. Therefore, the various proposals directed, in actuality, toward abolishing tank troops in their present organization, do not strengthen the ground troops in any way, but push us towards the French tactics which failed completely in the last war. We need powerful and well-organized tank troops - all the experience of the last war speaks eloquently of this, and it is demanded by modern conditions of carrying out combat operations arising as a result of the appearance and development of missile troops and nuclear weapons.

1.3(a)(4)

From the Editor

With a view to activating theoretical discussions of the most important and pressing problems of Soviet military science, and above all of military art, according to the decision of the Minister of Defense of the USSR, Marshal of the Soviet Union R. Ya. Malinovskiy, in addition to the Secret Collection of the Journal "Military Thought" which is being published at present, a Special Collection stamped "Top Secret" is being initiated.

The leading personnel of our Armed Forces, from the troops, military academies, the chief and central directorates, and the General Staff, are invited to write articles for this Collection. Obviously the leading personnel of the Soviet Army and Navy, who have the best theoretical preparation, the greatest practical experience, and the widest horizons, can contribute most to the development of Soviet military theory in the light of the requirements of modern warfare.

This Collection will be sent to a limited circle of officials, from army commander upward according to a special list.

The creation of a new Collection was dictated by the desire to ensure responsible authors of an opportunity to express their ideas, proposals, and critical remarks on all immediate problems of military theory in a more restricted circle, which would be difficult to do in other printed organs.

The Collection should be regarded as a continuing forum for articles, in its way, a military-theoretical conference by correspondence.

The fundamental methodology of articles on the pages of the Collection should be sharp, controversial, and forcefully argued formulation of the most vital theoretical problems and a creative discussion of them. Depending on the elaboration and clarity of the various matters discussed, there will be published conclusive articles which we propose to invite the most competent individuals, collectives of creative authors, and, when necessary, official organs, to write.

The most urgent task of our military-theoretical thought is to overcome certain antiquated views, and to scrutinize boldly, on the basis of a feeling for new developments, the changes taking place in military affairs. Such an approach will assure the clear understanding of realistic courses of the further development of Soviet military

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

science, and vigorous, creative elaboration of pressing, new problems of military art as regards strategy, operational art, and tactics, as well as problems regarding the structure and organization of the Armed Forces and of the development of military equipment.

Military-theoretical thought should look ahead boldly, vigorously pave the way to the new and progressive, refute decisively preconceived points of view, and evaluate critically the experience of the past.

As N. S. Khrushchev emphasized, "Under modern conditions, wars will not be waged as before and they will hardly be comparable to former wars." These new aspects of modern warfare, and their dissimilarity to previous wars, indicate with conclusive force the necessity which has arisen of examining from all aspects the qualitative changes which have occurred in military affairs. It is necessary to define the trends of their further development, to subject to a serious and decisive review the established theoretical viewpoints regarding questions of the conduct of war and military operations of all scales, of training, organization, equipping of the Armed Forces, and the gamut of other similar questions, the understanding of which has been predicated up to now to a significant degree on the experience of the last war.

It is envisaged that the theme of the Collection will be to examine problems relative to the nature of modern warfare, methods and forms of conducting armed combat, the use in it of all modern scientific - technical potentialities and means, of the types of Armed Forces individually and in coordination, and the employment of various means of mass destruction.

Particular attention should be paid to the examination of the nature, preparation, and conduct of operations of all types, particularly missile, under the various conditions of the probable theaters of war (TVD), and the strategic, operational, and combat employment of missile large units and units. It is necessary to elaborate on offensive and defensive operations of formations of the ground forces, air forces, the navy, troops of the PVO, and airborne troops, with exposition of those features and peculiarities which the use of the means of mass destruction and the conduct of missile operations inject into modern armed combat.

It is necessary to have an over-all analysis of the problem of modern combat with due regard to that particular influence which will be exerted on it by modern means of combat which will be employed by the higher command in the interest of conducting operations and the war as a whole.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

Particularly worthy of serious study and detailed elaboration are the problems of operational and combat support, among others, intelligence, protection of troops from the means of mass destruction, and radio countermeasures.

A large part of the pages of the Collection should be taken up by questions regarding the control of troops throughout all elements and echelons. Problems related to these questions are particularly important because the greater independence of action of strategic groupings in the TVD, operational formations, and tactical large units and units, complicates to a great degree, and gives special features to, the control of troops. Also entering into the framework of these questions is elaboration on the best forms of organizing the organs of control in all areas, the methods of their work, equipping and outfitting, using various means of automation, and problems of planning military operations.

It is very important to analyze as carefully as possible, and to elaborate, problems relative to the organization of the modern Armed Forces rear, of the field army and operational and tactical groupings of troops, from the point of view of maintaining uninterrupted supply to the troops of all necessary support for combat and life under conditions of continuous and powerful action against the rear by the combat means of the enemy; and the related problems of defense and protection of the rear and the coordination of operations in this area between the Armed Forces and civilian organizations. Also belonging to this group of questions is the problem of the preparation of the theaters of war and material reserves of all types and designations.

It is necessary, on the basis of profound analysis of the methods and forms of modern military warfare, to study and develop proposals for the future make-up of the Armed Forces and their organizational structure at all levels, and questions of the organization and methodology of training troops and command cadres.

Great importance may be attributed to proposals for further development of military technology, weapons systems, correlation of various types of weapons, vehicles, and mechanisms, and recommendations for further improvement of the old, and designs of new, models, based on the trends of development of technology.

The editors turn to the readers of the Collection, who should actually be its authors, with the request to participate widely and actively in the work of this publication and to submit articles which pose important problems and which propose realistic solutions. 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Taking into account the limited size of the Collection, the editors request the authors to make the articles as short as possible, to avoid redundancies and the commonplace, and at the same time, to argue convincingly their stated positions.

The Collection, with a volume of 8 to 10 quires, will be issued periodically. In the current year, it is proposed to publish 4-5 issues. In this first issue of the Collection are included articles which are most suited to the goals of this publication , chosen from articles received previously by the editors.

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

From the Editor

Articles of the Special Collection of the Journal "Military Thought" (Voyennaya Mysl) are published as a discussion and express only the opinion of the authors on the subjects which are broached.

All articles for the Collection, as well as inquiries regarding its publication, comments on published materials, and remarks regarding them, should be sent to the chief editor of the journal "Military Thought," following the rules for transmittal of Secret materials.

The present issue of the Special Collection of Articles of the Journal "Military Thought" is being distributed to army commanders and higher, according to a special list.

Chief Editor General-Leytenant Radetskiy, N.A.

DATE OF INFO: 1961 (Prior to May)

APPRAISAL OF CONTENT : Documentary

SOURCE: A reliable source (B).

Following is a verbatim translation of an article titled "The Organizational Structure of Field Command of a Front", written by Colonel K. Pashuk, Chief of the Operational Directorate of the Headquarters of a Military District.

This article appeared in the 1961 Second Edition of a special version of VOYENNAYA MYSL (Military Thought) which is classified TOP SECRET by the Soviets and is issued irregularly. The 1961 Third Edition went to press in July 1961.

The Organizational Structure

of

Field Command of a Front

by

Colonel K. Pashuk, Chief of the Operational Directorate of the Headquarters of a Military District

The very great changes which have been taking place in the postwar period in the means and methods of armed conflict and, under the influence of these, in the organizational structure of troops have not, in fact, affected command elements (organ upravleniya). The organization of field command of an army and of a front has remained essentially the same as it was in the years of World War II. Certain additions and changes which have taken place in recent years have brought nothing basically new to the organization of field commands.

The organizational structure and equipment of operational staffs (shtab) which exist at the present time have resulted in a certain contradiction with modern requirements. They limit the combat capabilities of troops, and they are in fact a brake on the achievement by the troops of high speeds in the conduct of operations. This is evident if only from the following.

The presence of nuclear-missile weapons in a front permits the fulfillment of operational tasks, not to mention tactical tasks, in a matter of minutes. Yet to collect and collate the facts of the situation in the headquarters of the front takes several hours, and is even then an excessive strain on its officers.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

At the present time, combined-arms large units (soyedineniye) are at constant combat readiness, determined by the time necessary for the assembly of a large unit when the alert is received and for its movement out from its permanent disposition (dislokatsiya) points. Army headquarters (shtab) however do not possess such a degree of readiness and, in general, are insufficiently adapted to work under field conditions, which, naturally, limits the combat capabilities of army formations (obyedineniye).

The most important conditions for ensuring firm control of troops are high mobility, the maneuverability of headquarters (shtab), and their effective anti-atomic protection. But how can there be talk of anti-atomic protection, of mobility, or of the maneuverability of the headquarters (shtab) of a front and an army if they are billetted in a tent camp on exercise? This situation is considered normal, for during critiques of exercises one can hear observations and objections only to the fact that there are very many tents and that they are not in the right order.

A broad discussion of the questions of organization and equipping of the elements for the control of troops and of the organization and equipping of control points (punkty upravleniya) is necessary. It seems to us that without the correct solution of these questions it is impossible to achieve a significant increase of the combat readiness of troops.

In our article we deal with several questions of the organizational structure of a field of a front. First of all, we will attempt to define the basic principles upon which this structure must be based.

In our view, the organizational structure of a field command of a front must proceed from the release of the commander of troops of a front, to the maximum extent, from the decision of questions which are not directly connected with the combat activity of the troops.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The commander must have sufficient time for study and for the choice of the best methods of deciding the basic current and future (perspektivnyy) tasks of the operation.

With the existing organization, this requirement is not met. In the front field command there are 18 independent directorates, staffs (shtab), and departments (otdel) subordinated directly to the troop commander. Under such an organization, the troop commander is compelled to cut himself off systematically from the immediate direction of operations and to decide a mass of questions of secondary importance. It is completely understandable that he is not in a position to listen to all those making reports and to give them exhaustive and concrete instructions. Besides this, with the existence of such a quantity of departments in the front field command, the solution of any question by one of the departments requires its coordination with numerous other departments, which leads to a great waste of time and effort. In consequence, the front field command works for a considerable time not for the troops but for itself, which does not help the operational efficiency of the direction in any way.

In order to ensure stable and continuous control of troops, given the present means and methods of combat, the front field command must be streamlined to the maximum. The large and unwieldy headquarters (shtab), with the complements we use at present, would be unequal to the tasks of firm control of troops in the first serious test. Clumsy and immobile, they provide a system of no more than superficial and seeming control of troops, to say nothing of their vulnerability, and of their consequent short tenure of life. How can one talk of the operational efficiency and mobility of the front field command, if its composition, not counting servicing personnel, considerably exceeds 1000 men? In our view, the strength of the command of a front should be reduced by at least 3-4 times. However, this will be possible only if the maximum use is made in the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

front field command of the various means of automation. Without this, under present conditions, it is, in general, difficult to achieve real operational efficiency in the work of headquarters and to eliminate multiplicity in the control of troops.

In speaking of the means of automation, we have in view, first of all, those means whose introduction is already entirely possible at the present time; selector communications (selektornaya svyaz), portable recording equipment, facsimile telegraphy, television communications, speech secrecy apparatus, duplicating apparatus, the simplest computing apparatus, etc.

Let us take one of the duties of the headquarters of a front - the collection and collation of facts about a situation. How many channels do one and the same set of facts pass through before they reach the troop commander of the front, and how much effort does the gathering of these facts cost? The troop commander of the front hears the reports of the army commanders (komandarm) or of the commanding officers of large units by high-frequency (VCh) telephone or other communications means. The chief of staff of the front hears the reports of the respective chiefs of staff by telephone (normally also by VCh) or, more rarely, by radio. The operational department (otdel) collects the facts of the situation through chiefs of directions (nachalnik napravleniya) and their assistants by telephone, radio, and telegraph, with the help of the communications officers. Commanders and officers of troop arms are engaged in the collection of the facts of the situation through their channels of communication. All these people receive the data at various times, in varying completeness, and with varying authenticity; the obtaining of the complete facts wastes too much time. It goes without saying that such methods of operation do not correspond to present-day requirements. The facts of the situation should pass from the troops to the front headquarters by the shortest possible route, and all work on collection and collation of these facts should occupy a minimum of time.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The organizational structure of a front field command should reflect the specific nature of the functions of this control link (zveno). As is known, the front troop commander, the army commander, and the corps commander decide questions which are essentially different from one another.

The corps commander is interested in the progress of combat operations directly on the field of battle; he is concerned primarily with changes in the progress of these operations. The army commander is interested in the ways in which combat operations are likely to develop over several days. Using the resources of operational intelligence (razvedka), he follows the movement of the enemy's reserves and means for nuclear attack and thus comes to understand the situation more deeply.

The front troop commander has available intelligence resources which allow him to follow the situation in the entire depth of a strategic direction or of a theater of military operations. His fundamental efforts are directed to the solution of long-term questions which will ensure the successful development of the whole operation. In conjunction with this, in the command of the front, the questions of the use of nuclear-missile weapons and of rear support of the operation are decided in their full scope, demanding of the staff and command of the front, as a whole, long-term planning, foresight, and, consequently, work of a completely different scope and content from that of an army headquarters.

At the same time a front headquarters cannot limit itself to a purely general knowledge of the operational situation. It should ensure that the front troop commander is constantly provided with facts about the entire current situation in the area of the front, because the front commander has at his disposal nuclear-missile resources which enable him to influence vigorously the successful decision not

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

only of operational but also of tactical problems at any time.

The organizational structure of a front field command must reflect completely the decisive role of nuclear-missile weapons in the achievement of the aim of an operation. The front troop commander should have an element which concerns itself both with the solution of questions of the use of missile troops in an operation and with the assurance of direct control or command of units and large units of these troops.

Besides this, since nuclear warheads (boyepripas) are at present delivered to the target not only by missiles but also by aircraft and by other means, and also in view of the fact that the radiation situation will exercise a considerable influence on the progress of combat operations, the front field command should include an element which is concerned with the general and specific planning of the use of nuclear weapons, with careful study of the radiation situation in the area of the front and of its influence on the progress of the operation.

In the interests of stability of control of troops, the organizational structure of the front field command should ensure its division into several echelons (echelon), the real independence of each echelon in the control of troops, rear units, and establishments, and the ability of the second echelon if necessary to take upon itself the control of the troops of the front and to exercise this control, even if only for a short time.

The front field command should be able to detach a small operational group of officers with means of control, which could ensure control for the troop commander during his movement to an advanced or auxiliary control point. This operational group should be constantly welding itself together even while performing its district (okrug) command functions,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

and should have special field headquarters equipment and corresponding means of communication.

It is clear to everyone that the existing structure of the front field command does not fully meet the requirements enumerated above and needs considerable improvement. Which are the main changes which need to be introduced into this structure?

First of all, the organization of a front headquarters as the basic nucleus of field command must be changed. The new organization of the headquarters should ensure anew the solution of such problems as the collection, collation, and recording of all data on the operational situation. In our view, a special element should be set up for this, which would be free from all other commitments. This can be the operational center of the operational directorate of the front headquarters. Only this center must be concerned with collection and collation of all the facts on the situation and with their uninterrupted transmission to the commander, to the chief of staff of the front and also to other interested persons and establishments, about which we will speak later. All remaining directorates, departments, and services are freed from carrying out this function and concern themselves with their particular questions. The operational center should be equipped with modern means of communication, with radio speech-secrecy apparatus, facsimile telegraphy sets, receiving and transmitting sets (teleustanovka), sound-recording apparatus, and selector communications. In the future it must have electronic computing machines which would automate such processes as:

- the collection and storage of facts on the position, state, and actions of enemy troops, and about the enemy's nuclear resources and their capabilities;

- the collection and storage of facts on the position and state of friendly troops;

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

- the systemization and collation of information on the operational situation for reports to the command and the higher staff;

- the processing of data on the radiation situation, the determination of areas contaminated by radiation, and of the levels of radiation for a given time.

The facts received by the operational center about the position of the troops (friendly and enemy) should be disseminated continuously by television sets or by telephones with visual presentation (videotelefonnaya svyaz) to the troop commander, chief of staff, and the department of operational planning. If necessary, the front troop commander or the front chief of staff can be at the operational center personally for the detailed solution of the most important questions of control of the troops.

Regular information about the position of the troops in the detail necessary for the solution of questions by the arms of troops must be passed by a special relay network for the remaining directorates (departments).

The operational center must have at its disposal several shifts (smena) of trained officer-operators. Each shift should also include an officer of engineer troops, one from the chemical troops, one from the hydrometeorological service, and representatives of the VVS and PVO control points. The shift should be headed by a responsible officer-operator (chief of the operational department) who can make an evaluation of the operational situation and pass it on at the proper time to the chief of staff or to the commander so that a decision can be made. With three working shifts and one reserve (for the forward command post-PKP, or auxiliary control point-VPU) there may be no more than 25 officers on the staff of the operational center.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The operational center cannot concern itself with questions of planning an operation; for this a special element is necessary - an operational planning department. Receiving systematic data about the current position of the troops from the operational center, the operational planning department analyzes and checks the fulfillment of tasks by the troops of the front, prepares suggestions for the command on the conduct of combat operations, and passes on the necessary operational tasks to the troops. In the future, the department of operational planning should also be equipped with an electronic computer, which would lighten the performance of such tasks as:

- the production of estimates related to determining the relative balance of forces and the regrouping of troops;

- the determination of the requirements for combat means either for a complete operation or for part of one and the distribution of these means to directions;

- the distribution of nuclear means by targets, the determination of the best alternatives for destroying enemy targets with the means available, and others.

When modern means of control are available, the execution of the functions entrusted to the department does not call for a large number of officer-operators. The staff of the department can be within the limits of 10-12 men.

The operational center and the department of operational planning should be united in a single element - the operational directorate, which would ensure unity in the work of these two bodies.

The intelligence directorate does not lose its significance, but remains a component part of the headquarters of the front. But since a part of its functions (the collection, collation, recording, and storage of data about the enemy which comes from the troops) is carried out by the operational center,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the complement of the intelligence directorate may be reduced and its structure changed. At the same time it is necessary to bear in mind that data about the enemy reaches the front headquarters not only from the troops but also from other sources: from the Chief Intelligence Directorate, from the intelligence directorates of neighboring fronts, from agent intelligence, from special diversionary-reconnaissance groups, from front radio and radio-technical intelligence, etc. This data should be checked, compared, and evaluated by the intelligence directorate before being passed on to the operational center, and for this it is expedient to have a special element - a control point for operational intelligence.

This control point, like the operational center, should work round the clock, and should therefore have three duty shifts and one reserve shift. Each operational shift should include two operational intelligence officers, concerned with the collation and analysis of all intelligence data, one officer from agent intelligence, one officer of radiotechnical intelligence, one aerial-reconnaissance officer, and one special communications officer.

To direct combined-arms reconnaissance and the planning and control of all types of intelligence activity in the intelligence directorate, besides the control point for operational intelligence, it is necessary to have another department for planning and control, with a staff of officers of combined-arms and operational intelligence, agent-intelligence officers, and radiotechnical intelligence officers.

We see no need for basic changes in the structure of the other departments of a front headquarters (replacement, communications, or topographical). However, the strength of each can be reduced considerably in connection with the possibility of automating and mechanizing their work. The role of the cipher department obviously will decrease with the introduction

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

of apparatus for ensuring the secrecy of radio, telephone, and telegraph conversations and, consequently, its strength, too, can be reduced.

The questions of the control of artillery in a front should be decided anew. The trend of development of combat means shows that the role of artillery in the solution of operational tasks is decreasing. Clearly, artillery will perform only tactical tasks. As a consequence, the need for the presence in the front field command of an element which would concern itself specially with the operational use of artillery is disappearing. Questions of the combat use of artillery can be settled successfully at the tactical level (zveno). Clearly these questions will be decided in exceptional cases in the front command.

At the same time, the ever-increasing role of missile troops in the resolution of operational tasks requires the presence in the front field command of a special element, which would concern itself with their direct command, not only operational, but also tactical control. Furthermore, we believe that this element must concern itself with the direct command of missile large units and units. Such an element can be the control point of the missile troops of the front. It should have direct radio, telephone, and telegraph communications with all missile large units and units of the front, and also selector and visual telephonic communication with the operational center and the operational intelligence control point.

The personnel of the control point of missile troops must ensure its unbroken work round the clock and also the detachment, when necessary, of a small but harmonious group of officers for the control of the missile troops during trips by the chief (nachalnik) of the missile troops to the PKP or VPU with the front troop commander. Hence, the control point of the missile troops can consist of three duty and one reserve operational shift. Each shift would consist of two

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

operators for the preparation of data and two control officers. The work of each shift can be headed either simultaneously or in turn by the chief of missile troops, the chief of staff of the missile troops, and by the deputy chief of staff of the missile troops (he is the chief of the control point and chief of the operational department).

The operational department of the staff of the missile troops has the functions of planning the utilization of the missile troops, of supporting them, of organizing reconnaissance, and of overseeing their combat activity. In view of this, besides the chief of the department, the operational department needs a deputy chief of department (he is the chief of reconnaissance), three senior planning and control officers, two senior intelligence officers, the chief of communications, and his deputy.

It is clear that no one will doubt the need for the presence in the front field command of an element which is concerned with questions of antiaircraft defense. However, its organizational structure must also be changed somewhat. The development in the capabilities of antiaircraft missiles and of radio-technical troops and the use of nuclear weapons to combat means of air attack, call for still more centralization of the control of the forces and means of PVO at front level. The need is growing continuously for their direct command by the front PVO commander. Hence, we consider it expedient to have a PVO control point in the front field command, equipped with modern means of control, which performs all tasks, beginning with the planning of air defense and ending with the direct control of PVO troops in battle. This point must be commanded by the chief of PVO troops of the front or by his deputy and should be set up on the principle of continuous operation by three shifts and should have a reserve shift for the control of PVO troops during trips to the PKP or VPU.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The controlling bodies of the engineer and chemical troops must, in our view, remain in the front field command. Their numerical strength can be reduced considerably since a part of the functions which previously belonged to these departments will be performed by the operational center, and also because of the possibility of equipping these departments with means of automation. However, there is no need to have these departments in direct subordination to the front troop commander. They decide questions of support of the combat operations of the troops, and their work should be more closely linked with that of the operational and intelligence directorates of the front headquarters. The operational center will concern itself with the collection, collation, and recording of data on the position, bringing up to strength, and condition of the engineer and chemical troops and of engineering and chemical equipment, and the front headquarters will also deal with the preparation and delivery to the troops of orders concerned with the combat use of engineer and chemical troops. All this points to the expediency of including engineer and chemical departments in the make-up of the front headquarters.

It is expedient that the unification in a single directorate of the elements dealing with questions of automotive servicing and of tank armament which has now taken place in the command of a district (okrug) should also be retained in the front field command with direct subordination to the troop commander.

It is expedient to concentrate all questions of the organization and structure of the rear, and of the material and medical support of the combat operations of the troops in one body - the directorate of the front rear services, headed by the deputy commander of troops for the rear services. The organizational structure and numerical composition of the directorate of the rear services should be examined with a view to cutting them down considerably. The nucleus of the directorate of the front rear services should be the rear-services operational center organized in

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

a manner similar to the operational center of the front headquarters. The rear operational center must decide all questions of collection, collation, and recording of data on the position and state of rear units and establishments, supplies of equipment, support to the troops, the structure of the operational and troop rear areas, and others.

It should be constantly ready to pass this data to the chief of the rear services and also to the operational center and to the chief of staff of the front. The chief of the front rear services is the person who reports to the front troop commander on questions about the rear services. In the future the rear-services operational center should be equipped with means of automation, which would facilitate the solution of such questions as:

- recording the availability and movement of material-technical means and the compilation of estimates of the requirements of the troops for these;

- planning supply and evacuation of all types, using the various types of transport present in the front, armies, and large units;

- recording medical losses, the degree of fullness of the medical establishments, the movements of wounded and sick, and others.

The strength of the political directorate of a front, whose subordination should remain as before, can be reduced because of the transfer of the functions of supply to the chief of the front rear services and of the functions of recording, appointing, and moving Party-political worker cadres to the chief of the directorate of cadres of the front. The strength of the directorate of cadres can also be reduced considerably because of the availability of computers which allow the automation of work on the registration of the cadres by the officer complement.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Such, in our opinion, are the changes which it is necessary to introduce into the organizational structure of the front field command.

Proceeding from this structure, it is by now already possible to define in its general outlines the composition of the command post of a front. It, obviously, will consist of two basic groups and one reserve group.

The first group: the commander of troops and the chief of staff of the front, the operational center, the department of operational planning of the operational directorate, the operational intelligence control point, the department of planning and control of intelligence, and the 8th department.

The second group: the headquarters of the missile troops, the control point of the PVO, the department of engineer troops, the chemical department, and the signals department.

The reserve group of the command post includes - the reserve shift from the operational center, the reserve shift from the control point of missile troops, the reserve shift from the intelligence control point, and the reserve shift from the PVO control point.

The reserve group serves to man the PKP or VPU. It can serve as the nucleus for a new front field command, if the command post goes out of action as the result of a nuclear strike by the enemy.

In conclusion, we shall dwell briefly on the organization and movement of the control points.

The organization, disposition, and movement of the control points must meet the requirements for stable and uninterrupted control of the troops under any enemy coercion. However, the present material base of our operational headquarters does not allow these requirements to be met. The experience of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

exercises shows that even if the control of troops is maintained on a sufficiently high level in the period of preparation of an operation, it very often breaks down during the course of the operation. As soon as the troops of the front are set in motion, control over them becomes insufficiently stable and the control points become helpless.

The relief of control points is carried out by old methods, by the dispatch forward of operational groups to organize control points in a new place, because, since they are on the move, operational headquarters are not in a position to control the troops. Consequently, when an operation is moving at high speed, headquarters fall behind the troops already by the second day.

In modern operations, the headquarters of a front should assure the commander reliable control of the troops irrespective of whether it is stationary or on the move. The control resources of a front headquarters must ensure reliable communications and the conditions necessary for the work of officers on the move, and its staff and material base should ensure the rapid establishing, closing down, and movement of control points.

Unfortunately, questions of working convenience and of rest for the officers of the operational headquarters have not yet been solved by us. Even the experimental models of radio trucks which are being developed for operational headquarters at present do not allow officers to work in them with a map. In consequence, there can be no talk of any control on the move or during a short halt. We have not one acceptable production model of a staff vehicle for operational headquarters. Attempts by the headquarters of districts and armies to get out of this situation by their own efforts and resources lead to the unreasonable waste of considerable sums and to the weakening of other links of the military machine.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In our opinion it is advisable to perform the task of developing a staff vehicle in a centralized way. The design bureau of any automobile plant could do this successfully within a few months. The establishment of normal conditions for the work of officers of operational headquarters will raise the quality and operational efficiency of their work and, consequently, will improve the control of troops as a whole.

A TURNING POINT IN THE DEVELOPMENT OF SOVIET MILITARY ART

Colonel-General Ye. IVANOV.

The discussion which has unfolded in the pages of the special Collection of Articles of the Journal "Military Thought" concerning the most important questions of military theory, is a notable and, in its significance, a very important, event in the military-scientific life of the Armed Forces.

This article also intends to present certain considerations on the essence of a series of questions, the examination of which, in our view, provides interesting topics for further broadening the discussion.

A CRISIS IN MILITARY ART OR A TURNING POINT IN ITS DEVELOPMENT?

In the recently published articles of certain authors, the question is posed that there have been no serious changes whatsoever in Soviet military science since the end of World War II, and that in essence it is undergoing a crisis.

"Dropping curtsies in the direction of missiles and introducing some minor corrections in the theory of military art, we still hold in practice to the old positions existing at the end of World War II. Past experience, traditions, and habits taught to us for decades, tenaciously hold us back and prevent the same kind of revolution in military art which nuclear weapons and missiles created in the sphere of armament"[1], - states Colonel-General Gastilovich. He, like certain

[1]Special Collection of Articles of the Journal "Military Thought", first issue, 1960, page 6.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

other authors of articles published in the Collection, adheres to the view that the question is no more than one of adapting old forms and methods to new conditions.

It is quite obvious that such a presentation of the question is far from an objective evaluation of the state of development of Soviet military art.

Military art, being a category of history, is subject in its development to the general laws of Marxist dialectic. Therefore, it is subject in the fullest sense to the general dialectical law of development, expressed as a transfer from quantity to quality. It manifests itself in all the processes of nature, society, and thought - everywhere, where the change from old to new is under way, including the development of military affairs.

With the appearance of nuclear weapons, it has been, of course, more or less clear to everyone that they constitute a new and extremely powerful weapon, heralding the beginning of a revolution in the means of armed combat and the ways of conducting it. This revolution is going on gradually and in accordance with the development of the means of combat. It is impossible to accomplish it in a limited period of time.

Therefore, there is nothing surprising in the fact that five or six years ago, when our deliberations on the conduct of operations were based on two or three dozen nuclear weapons which could be delivered to their objectives only by aircraft, the discussion obviously could realistically concern only a partial "modernization" of certain aspects of military art, because many facts which only became known later were lacking for another approach.

The appearance of new means of combat, as the experience of military history testifies, only brings

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

about radical changes (a revolution) in military art when these means are introduced into the armament of troops on a mass scale, and when by these means it proves possible to accomplish a majority of the tasks arising during military operations, but this always required time. Fundamental changes in military affairs have never been accomplished with lightning speed.

In this regard it should not be forgotton that throughout the entire history of class society, the equipping of armies with new types of armament and combat equipment has, in all countries, come up against the definite limits of their economic potential, and therefore, notwithstanding the great desire of certain military figures, the process of transformation from old means of combat to new has been accomplished gradually over a definite period of time whose duration depended primarily on the productive potential of the country concerned.

In this connection, along with new means of combat, the old means continued to be used as well, from a necessity dictated not only by combat but also by economic factors.

Therefore, one should not be surprised by the fact that along with newly formulated views of military theory, the old naturally also continue to exist for a definite period. In the postwar period, a constant process of perfection of conventional types of armament, as they have now come to be called, was carried on in our armed forces. The advent of nuclear weapons and the improvement in their combat characteristics, together with the yearly increase in their scale of production, was a constant process of accumulation of qualitative and quantitative changes in the means of armed combat and consequently in the methods of waging it.

This process of development is not only as yet incomplete, but on the contrary, embraces an ever

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

growing field and continues to bring about ever-newer situations in military art. Nevertheless, this does not mean that certain views have not already been formulated on specific problems. It should be noted that in recent times, on the basis of theoretical research and general conclusions from the practical experience of troops, we have developed and put into effect new field service regulations, combat regulations for the various arms of troops, and instructions on the combat utilization of special troops. A great deal of work, which has on the whole been a positive contribution, has been done in examining questions of the conduct of combat and operations, especially during the initial period, employing new means of combat. During this time, our industry, on the basis of principles developed scientifically and confirmed by the Party and the Government regarding the future structure of the armed forces, and in accordance with these principles, was given the means to undertake on a mass scale the equipping of troops with missile/nuclear weapons. To ignore all this and to write about a "crisis" is to ignore all those progressive changes which have taken place and are taking place in the development of Soviet military art.

All that has been said, of course, does not mean that our military theory has already fully resolved all questions and that we have avoided all miscalculations.

Marshal of the Soviet Union Malinovskiy, in a speech at the All-Army Conference of Secretaries of Primary Party Organizations, said: "We must say directly, that in a whole series of questions we have not shown the necessary creative power, scientific daring and boldness, if you will, but have long been marking time".

Therefore, in the interests of the work itself we must talk not of a crisis in military art, which we absolutely do not and cannot have, but of those weak

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

points in military theory which are in fact at the turning point in their development.

FOR WHAT TYPE OF WAR MUST WE BE PREPARED?

One of the most important questions raised in the pages of the Collection, is the question of Soviet military doctrine. The increased interest in its development is completely understandable. At the present time our armed forces find themselves at the turning point of their development; therefore, a further intensive analysis of military doctrine naturally assumes paramount significance.

M.V. Frunze, defining the concept of "a unitary military doctrine" pointed out that it is a "syllabus adopted in the army of a given state, which establishes the nature of the structure of the armed forces of that country, the methods of combat training of troops, their leadership on the basis of the predominant views in the state on the nature of the military problems facing them and the means for solving them, and which emanates from the class nature of the state and the computed level of development of the productive forces of the country".[1]

From the definition it is apparent that M. V. Frunze places prime importance on the question of the nature of the structure of the armed forces, which depends above all on the level of development of the productive forces of the country, on its economic potential. The question of the economic potential of our country arouses no doubts in any of us. Our

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

socialist state is in a position to provide the armed forces with all presently known means of armed combat.

However, there are examples in military history when economically strong countries, not lagging behind their adversaries with regard to the equipping of their own armed forces with weapons and combat equipment, have yet suffered most devastating defeats.

Why? In a number of cases this occurred because military-theoretical thought in the prewar years could not correctly resolve the question of the type of war for which its armed forces should be prepared.

For example, prior to World War II the armed forces of France and fascist Germany had approximately the same level of equipment in aircraft, tanks, and artillery. However, France suffered a swift defeat in the war. Among the host of reasons which brought about her capitulation to fascist Germany, of no small significance was, as is known, the fact that French military doctrine was based on the principles of defensive strategy, but the German, on offensive. Subsequently, as is known, fascist Germany also suffered defeat, while having as the basis of its military doctrine the adventurist idea of waging a blitzkrieg.

Consequently, to resolve correctly the question of the character of the structure of the armed forces, scientifically based recommendations of military theory are necessary, especially on such questions as the character and possible duration of a future war and also the methods of waging armed combat, which arise from the aims and objects of war as defined by the political leadership.

During the past few years, these very questions have been the subject of heated controversy.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

What conclusions, for example, are to be drawn from the ideas of Colonel-General Gastilovich on the nature of a future war, its duration in general, and its initial period in particular, "There is no need to fear the term 'blitzkrieg' .... Under the conditions of nuclear war only 'blitzkrieg' operations can promise victory." "Under present conditions the possibility of victory must be assured by the readiness, the capacity, and the capability of concluding the war in the shortest possible time. The theory of a prolonged war is more acceptable at present to the monopolistic circles of the West..." "Taking over the border zones and the zones of total destruction and radiation .. will not at all necessitate multi-million man armies". So writes Colonel-General Gastilovich.[1]

In almost the same spirit General Goryainov writes: "The missile/nuclear weapon has become (or can become) a mass weapon and its destructive and in particular its radiological qualities (a reference to megaton bombs - Ye. Ivanov) are actually capable of creating conditions in which the fundamental object of war - the destruction of the enemy - can be accomplished technically in a short period of time and without over-taxing the economy of powerful industrial countries".."just a few hundred powerful nuclear bursts will be the primary and decisive factors affecting the outcome of the war .. the initial period of a war becomes its decisive period."[2]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

If one were to summarize briefly all the quotations mentioned above, having cast aside certain reservations which the authors occasionally make with regard to ground troops and other types of armed forces, they could be said to be, essentially, exponents of an "atomic blitzkrieg". They consider that a future war will have a rapid, blitzkrieg character; its outcome will be decided by the first missile/nuclear operations for which only some few hundred thermonuclear warheads need be expended; that it is not necessary to have a multi-million man army for waging war, and the basic function of the small number of ground troops in a war should be confined to the occupation of enemy territory.

What would happen if these views were to be legitimized and raised to the status of fundamental principles of our military doctrine? First, our armed forces would be subject to one-sided orientation in their development, with all the consequences resulting from this, and secondly, in essence, we would be forced to abandon that versatile training of the troops which we now conduct, counting on a fierce and relatively extended armed conflict with the powerful coalition of the imperialist countries. Such an approach to the organization of the armed forces and their military training would be one-sided.

A future war in its political essence will be a decisive armed conflict between two world socio-economic systems - capitalist and socialist. A struggle between them will involve two of the most powerful military coalitions, armed as never before and possessing colossal material and manpower resources. Therefore, no matter what losses single governments would suffer in the beginning of the war, serious consideration must be given to the fact that a coalition of nations as a whole can prove capable of waging armed combat over a considerably protracted period.

Without a doubt, massive missile/nuclear strikes of a strategic nature in the very beginning of the war

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

will create conditions for the accomplishment, in the initial period, of results that bear no comparison with the results achieved during the initial periods of previous wars. Naturally, this will have a very great influence on the conduct and the general duration of the war.

However, to orient oneself in building the armed forces and preparing the country for a war in which the initial period will be decisive for the achievement of the ultimate goals of the war, would be completely unfounded.

Indeed, Comrade Goryainov admits to the possibility, and with this one cannot disagree, that once a war has begun, the situation could arise where the strategic missile troops of both sides, for a number of reasons, might be only partially successful in their aims and not achieve a decisive effect. For my part I will add: One cannot base one's estimates in war only on the availability of one's own means of destruction and not consider the means of destruction and counteraction open to the enemy, particularly the means of antimissile defense which are now being developed rapidly. We may guess at the enemy's plans, but it is he who carries them out, and his actions, as the experience of all wars can testify, usually introduce substantial changes in our plans. Therefore, in the evaluation of the initial period of a war and consequently of the direction of organization of the armed forces, we should not in principle base our ideas only on the possible decisive role of this period, but must be prepared for the continued conduct of numerous operations with all types of armed forces even in the ensuing periods of the war.

At the same time we certainly must not underestimate the definite role, in the light of known conditions, of the first operations of the initial period of the war and the possibility of destroying the aggressor in a short time.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

To deny this would be to stand out against a fully comprehensive approach to the preparation of our armed forces. In these questions there should be no extreme.

The Minister of Defense points out: Having ensured the security of our Motherland, we must develop and perfect the means and methods of armed combat with a view to achieving victory over the aggressor above all in the shortest possible time, but at the same time we must seriously prepare for an extended war, and this determines the direction of our military organization. Such is the only kind of approach to this question that we too can consider legitimate.

The basic content of the initial period of war can consist of: the disruption and repelling of the first blow of the aggressor on the ground, in the air, and on the sea; the inflicting upon him of a shattering blow designed to disorganize the governmental and military leadership and also the destruction of the most vital economic targets, especially industrial enterprises connected with the production of means for nuclear attack; conducting initial operations with all types of armed forces in close coordination in order to accomplish the most immediate military-strategic tasks and the early seizure of the strategic initiative.

The fulfillment of these tasks will doubtless create the necessary prerequisites for the swift conduct of the war and the achievement of final victory. But the prerequisites are not victory itself. Military history indicates that armed forces which have successfully started a war can in the final analysis end up vanquished, and the first blows suffered by an army at the beginning of a war still do not signify final defeat.

Consequently, it behooves us to take as our starting point the fact that for the successful conduct of, and final victory in, a war, colossal efforts of the armed forces and the entire state as a

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

whole may be required. Massive armies and the mobilization of all the moral and physical strength of the people and of the economy of the country will be essential.

A position in which the decisive role for the achievement of the primary objectives of the war is delegated to missile troops of strategic designation certainly does not mean a reduction in the utilization of ground troops, but on the contrary indicates a more important need for them on the basis of their potential capabilities.

It is incorrect to count on their being, as a result of the extensive utilization of missile-nuclear weapons on the field of battle, a completely dead zone, and that there will be nothing left for our troops to do but to move effortlessly into the heart of the enemy countries to carry out occupation functions.

For the final defeat of an enemy and the seizure of his territory following nuclear strikes by missile troops of strategic designation, regardless of how powerful the strikes might be, it will always be necessary to bring in a sufficiently large number of ground troops. Without this, it would be difficult to predict the possibility of concluding any kind of war.

Therefore, a very important role will belong to the ground troops in the attainment of the final aims of a war. They have all that is necessary to carry out this role. Their firepower and striking force, together with their supply of missile weapons with nuclear warheads, the full motorization of troops, and the growth in the relative importance of the tank troops have increased sharply and in consequence their significance in the light of the new conditions of armed combat has not diminished.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

THE USE OF MISSILE TROOPS OF STRATEGIC DESIGNATION

Prior to the placing of missile/nuclear weapons in the hands of the strategic leadership, there existed, in fact, no means by which the progress of a war could be quickly and decisively affected. Even in World War II, although our bomber aircraft could already deliver bombs of rather significant force, these could not be sufficiently powerful to have a swift and direct influence on the outcome of the war. Therefore, strategy achieved its goals through the successive waging of many battles, engagements, and operations, all leading, in the aggregate, to a specific strategic result.

An entirely new factor under present conditions is that such powerful means as various forms of missiles, among them intercontinental ones with hydrogen warheads, are in the hands of the strategic command. With the assistance of such means, the strategic command has the capability to fulfill directly and independently (and not only by protracted engagements and battles between ground troops as was actually the case in the past) in the very shortest period, exceptionally important missions, even to the destruction of a number of countries of our probable enemies, along with their armed forces, in any part of the globe.

Consequently, under present donditions, in order to decide correctly questions about the nature of operations and to determine the methods of combat operations of the troops in an operational element, it is necessary to clarify fundamental principles regarding the use of the strategic striking forces - the missile troops of the VGK (Supreme High Command).

Missile troops of strategic designation are the decisive striking force and the wielders of the strategic power of our armed forces. They will carry out the most important tasks in the disruption of the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

enemy rear, his economy, and systems of governmental control by destroying his strategic means of armed combat.

Given these capabilities, it may be assumed that they can be used suddenly, in mass, against the main enemies, with the intention of achieving a strategic result in a short period. In this sense, the most important objectives for strikes of the strategic missile troops will be the enemy's means of nuclear attack, against which it is primarily necessary to launch missiles of intercontinental and intermediate (srednyaya) range types, and also his strategic aviation, centers of governmental and military control, the most important economic objectives, especially those connected with the production of nuclear weapons, and other important aspects of his war potential.

The decision regarding the question of objectives, the timing and force of the strikes of the missile troops of strategic designation, is entirely and completely the prerogative of the Headquarters (Stavka) of the Supreme High Command, and will depend on the capabilities of the country to adopt missile/nuclear strategic weapons and also on the concrete conditions of the situation, of which the political factor will be the decisive element.

It is not the intention of this article to analyze the possible role of the High Command with missile troops in the organization and execution of the strikes which have been decided, but we would nevertheless like to emphasize that this role, in our view, should be kept within firmly defined limits, since every such strike is a most important factor of policy and strategy, and accordingly should be carried out in all its details on direct orders of the Supreme High Command.

In our theory, the question frequently arises of the participation of ground troops or their missile large units with the advent of war in "missile operations" of the strategic missile troops and, conversely,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

of the participation of the missile troops of strategic designation in the operations of ground troops. The posing of such questions has no sound basis.

Indeed, military-industrial objectives, the largest administrative-political centers, and the strategic means of nuclear attack of the imperialist governments, all of which are designated for destruction by the missile troops of strategic designation, are deployed over a great expanse of the globe. They are located in Europe, Africa, Asia and America.

In turn, our missile troops of strategic designation are also deployed over an enormous area. Therefore, under these conditions there is hardly any sense in speaking of the concept of direct coordination and execution of joint strikes by the strategic missile troops and missile large units (units) of the ground troops. We can only say that the successful accomplishment of their basic missions by the strategic missile troops will create favorable conditions for vigorous and decisive operations by all the other types of the armed forces, including the ground troops.

It is true that observations have been made to the effect that together with the execution of the missions enumerated above, missile troops of strategic designation will also be used for the accomplishment of such missions as the defeat of groupings of ground troops in a theater of military operations, the destruction of the enemy's operational means of nuclear attack, and other objectives. And in light of this, an attempt is made to analyze the bases of coordination between missile troops of strategic designation and missile large units of ground troops. It appears to us that such a presentation of the question is also devoid of a realistic base.

The efforts of missile troops of strategic designation should not be dissipated over numerous targets, just as in the years of World War II it was

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

considered irrational to use long-range aircraft for strikes against operational objectives. If we did so at times, then it was a case of extreme necessity because of a front's lack of aircraft.

To plan beforehand for the execution of operational missions by the strategic missile troops is not expedient. For this reason, the missile troops of the ground troops, continually being supplied with more highly perfected types of missiles, will be able to destroy enemy objectives to a greater depth than is now possible, and this will ensure the successful execution of front operations without the involvement of strategic missile troops.

The strikes of the strategic missile troops must, in the final analysis, predetermine the attainment of the principal goals of the war -- in this lies their fundamental purpose. Their basic efforts must be focused on the attainment of these goals.

ARE THE DISTINCTIONS BETWEEN OFFENSE AND DEFENSE BEING OBLITERATED?

If one were to analyze carefully the judgements of General Gastilovich, then it would not be difficult to come to the conclusion that defense as a form of armed combat has disappeared or is on the threshold of disappearing because it has somehow lost its inherent characteristic -- to hold designated lines or areas with the object of inflicting maximum losses upon the advancing enemy and, in doing so, to create the necessary conditions for a transition to a decisive offensive. He sees the distinction between defense and offense only in the number of nuclear weapons, of divisions, and the composition of echelons. As to the means of conducting combat operations, they are, in his way of thinking, the same in offense as in defense.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

"In offensive as in defensive operations of ground troops, the basis of their operations is nuclear strikes, swift maneuvers and short assaults with tanks and manpower".[1]

If one is guided by the materialistic dialectic and also proceeds from the actual relationship of the strength of the opposing military groupings, then it is obviously impossible to agree fully with these assertions.

We all acknowledge that offense will be the basic form of combat operations of our troops in a future war. But in acknowledging offense, we cannot deny the necessity for defense as one of the possible forms of armed combat, because if there is no defense then there is no offense. Offense is so called because it is waged against a defending enemy. Without the presence of a defending enemy the troops would execute a normal march. Offense and defense are two inter-related and interdependent forms of armed combat, and one cannot exist without the other. Such is the dialectic of this question.

In the judgements expressed above, it appears that consideration has not been given to the capabilities of our potential enemies.

Actually, the countries of the Socialist Camp are militarily, politically, and economically strong as never before. However, in preparing for war and exploring new methods of armed combat, we cannot assume that our probable enemies are not technically armed, as they say, to the teeth. They have multi-million man armies, they possess enormous stocks of nuclear weapons and modern means of delivering them to their targets. Therefore, to consider that we will not encounter serious counteraction from their side is a fallacy. Moreover, a new world war can only be unleashed by the imperialist aggressors, primarily by the Anglo-American

---

[1] Special Collection of Articles of the Journal "Military Thought", first issue, 1960, pages 12, 13.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

imperialists and the West German revanchists. Consequently, they will be the first to try to carry out a massive missile-nuclear attack which will be followed by an invasion of ground troops. The effects of a missile-nuclear strike can be very tangible not only for our country but for the entire Socialist Camp as well. The enemy can take the initiative in his hands in specific sectors of a strategic front and compel our troops to resort temporarily to defensive operations. Not to consider this and to reject completely the possibility of such a development in specific directions -- means to close one's eyes to reality, to indulge in "counting one's chickens before they are hatched" (shapkozakidatelstvo).

We maintain that a future war will have not only an all-embracing, but a many-sided character, with varied forms of armed combat. Consequently, our task does not consist of artificially simplifying them but of thoroughly studying currently existing methods of combat, of evaluating them objectively and correctly, and of devising new ones.

The more versatile the preparation of our armed forces from the point of view of their mastery of all possible forms and methods of armed combat, the higher will be their combat readiness and the greater will be our guarantee against any type of surprise or incident in the course of a war. Such is our understanding of this question of the plan for waging war.

But how does this question fare within the framework of an operation? Under modern conditions, defenders who are launching massive missile-nuclear attacks on an advancing force can in a number of cases change decisively the correlation of forces to their own advantage and force it to turn to defensive operations, and sometimes to retreat.

In this connection one of the characteristic features of an offensive operation in depth under conditions of mass use of missile/nuclear weapons is

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

the variety of forms and methods of waging it and also the dynamic nature of their change: swift pursuit and solid, vigorous defense, meeting engagements, and retreats, combat under encirclement and disengagement from combat -- such is the possible general picture of development in a modern offensive operation. Every form and method of armed combat has characteristics, peculiarities, and modes of conduct which are inherent to it alone. Therefore, the mission of military art is not confined to the artificial elimination of distinctions among them, nor to the forcible abolition or coalescence of methods but to developing a theory for their organization and conduct under conditions of a missile-nuclear war.

Much attention is devoted by certain authors to an examination of the methods of conducting defense. They consider that to defend oneself now is senseless. Nuclear weapons overwhelm and destroy everyone everywhere; it is unnecessary to hold areas and positions, just as it is impossible to maintain their stability.

In our opinion, defense on an operational as well as a tactical scale must be able to withstand enemy missile/nuclear strikes and the subsequent tank assaults to preserve to the maximum possible degree one's own personnel and equipment, to inflict the greatest destruction upon the enemy, and to create the necessary conditions for going over to the offensive and the final destruction of the enemy, even in a situation where the defending troops employ limited forces and weapons. Such a mission for defense under modern conditions is typical, the more so because the attacker will not always and everywhere have the capability to overcome the defense by massive nuclear strikes.

Can one, under current conditions, argue strongly for a defense based only on maneuver and strikes by forces located in the zone of the interior? Our reply to this is in the negative.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

Defense, with its inherent peculiarities and methods of conduct under modern conditions, must be built on a skillful combination of firm holding of definite areas of terrain together with maneuver and strikes by troops from the zone of the interior. Maneuver must be utilized mainly for the preservation of one's own limited forces and weapons, the creation of a firing line which is invincible to the enemy in the primary directions of his offensive and also for the launching of fire strikes and the execution of counterattacks and counterstrikes.

To relegate "stability of defense to the archives" as General Gastilovich proposes -- means to deny that premise on which is based the modes and methods of operations by troops in defense.

Such an assertion is all the more untrue if one keeps in mind that stability of defense is not exhausted by the creation of defensive positions and zones by the organization of terrain by engineer work. This is just one of the factors upon which stability depends. Stability of defense must be achieved by other factors as well, foremost by missile-nuclear strikes, strikes by troops and an extensive system of obstacles. Even formerly one could not talk about any sort of stability of defense without maneuver, fire strikes, and strikes by troops.

Missile/nuclear weapons in the hands [of defensive troops affords them the possibility of] completely frustrating [the enemy's offensive.][1] But this possibility in no way denies the necessity for the formation of defense according to a definite system. The deployment of troops in tactical as well as in operational elements must be subject to definite requirements and must guarantee not only the accomplishment of maneuver, but also the holding of basic areas in the probable directions of the enemy's offensive.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

Today there is a series of "weak spots" in our defense. Basing its organization on defensive zones and positions, to a large extent it retains a linear concept. The deployment of forces and weapons along solid frontal positions and zones gives rise in a number of cases, as experience in exercises demonstrates, to the desire to close the gaps and breaches which leads to the linear deployment of forces and the establishment of a continuous front.

As a result of the radical changes which have taken place in the means of armed combat and also in the methods of our probable enemies in conducting an offensive, the necessity for a reappraisal of the forms of organization of a modern defense has obviously arisen.

A defense strip (zone) of an army must obviously have a system of organized areas capable of withstanding massive enemy tank attacks, of disrupting the efforts of his ground troops, and of creating favorable conditions for inflicting on them not only nuclear strikes but also counterstrikes by our own forces from the zone of the interior.

Within a defense strip (zone) of an army, which can reach 150-200 kms and more along the front and 150-200 kms in depth, it is expedient to assign to divisions defense areas which embrace the basic directions of the probable offensive of the enemy.

In the defense strip (zone) of an army the following must be prepared, siting areas for missile large units, areas of defense for divisions; siting areas for units of PVO troops, areas of disposition and lines of deployment of large units of the second echelon and reserves; control points; a road network, and a system of obstacles set up by the engineers.

The area of defense of a division must also be a system of organized areas of defense for units deployed along the front and in depth along the most important directions. The size of the area of defense for a division can vary.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Within the area of defense of a division there must be organized siting areas for missile and anti-aircraft missile units, areas of defense for regiments and battalions, artillery fire positions, control points, and areas of disposition and lines of deployment of second echelons and reserves.

The area of defense for a regiment under these conditions can reach 10-15 kms along the front and 10 kms in depth, and for a battalion, from 3 to 5 kms along the front and 2.5-3 kms in depth. All areas of defense must be adaptable to perimeter defense.

The basis of organization of areas by engineer work should be primarily construction for fire means, cover for personnel and combat equipment, preparation in the antiatomic sense in combination with obstacles and roads in order to support a troop maneuver, and not the construction of a solid trench system. Sectors of trenches and connecting trenches can be established only in the areas of defense of subunits, and even there only if time is available. The intervals between areas of defense must be covered by fire, obstacles, and, on the most important directions, also by missile/nuclear strikes.

The organization of the defense must be begun with the organization of a system of fire which must guarantee: the destruction of the enemy's means for nuclear attack as they are discovered; the destruction of his troops and areas of deployment at the time of advance, deployment and, transition to the offensive; the repelling of massed attacks by enemy tanks and infantry; destruction of scattered enemy groupings; destruction of control points and his radiotechnical equipment; covering with fire the obstacles and areas of chemical contamination, breaches, open flanks, and areas subjected to nuclear strikes; the support of troops launching counterattacks and counterstrikes; the capability of concentrating fire in a short time in any threatened direction.

[redacted] 1.3(a)(4

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

It is essential to plan beforehand the areas of destruction by enemy fire both in the remote approaches and the main line of resistance, and on the flanks and in gaps, and in the depth of the defense, and also to prepare artillery fire for separate sectors.

CONCERNING THE COMPATIBILITY OF MISSILE/NUCLEAR STRIKES AND OPERATIONS OF TROOPS

Nuclear weapons are the main, most powerful, and most effective means of destroying an enemy carrying out any type of combat operations. Naturally, therefore, the results anticipated from their use must be the basis for solution of the question of using combined-arms large units.

However, missile/nuclear strikes in their turn should be carried out with the aim of creating more favorable conditions for troops to accomplish the final crushing of the enemy and to seize those areas and objectives which are designated as the aims of the operation. The troops must be prepared in such a way, and occupy such an operational position, as would permit them to utilize to the greatest extent the results of missile/nuclear strikes.

In this connection, we consider it necessary to dwell on the question of the selection of the direction of a strike by troops and of determining the timing of nuclear strikes.

The main efforts of combined-arms large units under modern conditions need not always focus only in those directions where the main bulk of nuclear weapons is employed. The concentration of the main efforts of the troops in the direction of the employment of the main bulk of nuclear weapons, in many cases, will not permit the speediest and most complete exploitation of the results of the action of all the destructive factors of nuclear strikes and the achievement of the maximum destruction of the enemy.

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Thus, during a breakthrough in the prepared defense of the enemy, with the objectives of achieving the maximum destruction of defensive installations, the destruction of combat equipment and personnel, the creation of high levels of radioactivity to impede the establishment of defense and the introduction of fresh forces, it can be incomparably more advantageous to employ surface or low altitude bursts. Under these conditions, the main efforts of the advancing troops will be more advantageously concentrated by bypassing the areas which have undergone a massive nuclear strike.

The concentration of the main efforts of troops in the direction of nuclear strikes can also prove inexpedient during an offensive through heavily wooded areas. Fires, log obstacles, the retention /two or three words missing/ of the /one word missing/ time of choosing /part of line missing/ of troops in the areas of nuclear bursts. In these cases, if only the possibility of envelopment exists, it is essential to use it decisively, and to effect the destruction of the enemy in the forest with powerful nuclear strikes.

A somewhat similar situation can take place if the attack comes through areas with large cities where the operations of troops after nuclear strikes could prove very difficult.

The direction of the concentration of the main efforts of combined-arms large units and of missile-nuclear weapons can also differ owing to the delineation of the line of the front. When a flanking position has been taken up in relation to the main enemy grouping, it will often be more expedient to concentrate the main efforts of the missile/nuclear weapons directly on this enemy grouping and to launch the strike by troops in an enveloping movement -- on the flank and rear.

There can be other conditions of the situation when the direction of the concentration of the main

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

efforts of the troops will not pass through areas of employment of the main bulk of missile/nuclear weapons.

Consequently in this question we are faced with a new law in military art, the essence of which consists of the fact that modern means of combat not only allow but very often obligate the separation, in relation to space, of the strikes launched by nuclear weapons and by troops.

This necessarily applies to considerations of the antiatomic protection of all forces and weapons designated for an offensive, as well as to considerations of the most effective use of all the destructive factors of nuclear weapons.

In determining the timing of launching nuclear strikes, we shall also encounter a new situation which cannot be ignored. As is known, in World War II, we did not usually begin artillery and air preparation if the troops were not completely prepared to advance. And how must we resolve this problem under present conditions?

In principle, it is desirable that the time for the launching of missile/nuclear strikes be determined after a consideration of the operational situation and of the readiness of the troops for the most effective utilization of the results of these strikes. This, however, is only in principle. If there is reason to assume that the enemy can effect a preventive strike, then it is essential to launch one's own nuclear strikes against him without delay, not waiting for the complete readiness of all the troops predesignated for the offensive, because every delay in the missile/nuclear strike in the beginning of the operation is fraught with the danger of its frustrating the offensive.

***

In conclusion, we consider it essential to emphasize once again that at the present time it is our deep

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

conviction that Soviet military theory is passing not through a period of crisis, but through a turning point in its development.

In the light of this situation, as it appears to us, it is also necessary to conduct a further elaboration of military doctrine, of the theory of military art, and of other questions of military affairs.

1.3(a)(4)

"THE USE OF SURFACE VESSELS IN MODERN NAVAL WARFARE"

BY REAR-ADMIRAL N. ZVYAGIN

The important qualitative changes taking place in the armed forces as a result of their being equipped with the newest combat weapons have changed the role and place in war not only of the types of armed forces, but also of the arms of forces and troops. In our Navy these changes are apparent primarily in that the submarine is becoming the basic striking force of the Navy.1

In this connection, various views are expressed as to the role and position to be occupied by surface vessels in modern naval operations. Often opinions are voiced to the effect that surface vessels have lost their significance, that they will be useless in a future war, and are therefore not needed by the Navy. Thus, there is no apparent need to build new vessels; one can still use the vessels of various types which still exist as part of the Navy; later, with the development of submarines, the need for the use of surface vessels in modern naval operations will fall by the wayside.

It is a fact that such large ships as battleships, cruisers, and destroyers, to give them their former designation, have completely lost all combat value and have no prospects of being used as a naval striking force. The role of the latter has been given to the submarines; in foreign navies this role will continue to be borne for some time by aircraft carrier striking large units, although even aircraft carriers no longer represent the force they used to be in the not so distant past (this is why the American high command puts such great emphasis on the development of strike submarines).

But, as is well known, the purpose of surface vessels was not exclusively to resolve combat missions through the use of large

---

1. The navies of the large capitalist countries have as their basic striking force large units of aircraft carriers, consisting of surface vessels and deck-based aircraft. In the near future the role of the main striking force will be assigned to the missile-carrying nuclear submarines, which are being built at an accelerated pace. The navies of the secondary naval powers are putting greater emphasis on the development of anti-submarine defense, which consists of surface vessels and anti-submarine aircraft and helicopters.

[redacted]

1.3(a)(4)

vessels. An important role was played by vessels of other types in support of the basing and deployment of naval forces, including submarines, in defense of naval communications and of the coastline from attack by enemy surface vessels, and also in resolving other missions.

Although submarines have become the basic arm of forces, they cannot always be used without the participation of other arms of naval forces. Submarines need support in their basing and deployment and, primarily, must be defended against enemy submarines. Of all the currently available forces and resources, special surface vessels are the most effective solution to these missions. In addition, there are some missions which in effect cannot be solved at all by other naval forces without surface vessels.

Therefore, we feel that although surface vessels no longer have the basic role in the Navy, they still are a very important part of it.

The missions of surface vessels under modern conditions have essentially changed. As already stated, in the near future the basic striking force of our probable enemy's Navy will be missile-carrying nuclear submarines. As the number of such submarines increases, the threat of the infliction of their strikes also increases-not only against our naval objectives, but against important industrial centers situated well inside our territory. Fighting against these enemy forces will be conducted by special submarines of the antisubmarine defense, aviation, and surface vessels.

For the present, as well as in the near future, the most effective solution of the mission of combat against enemy nuclear submarines can be achieved only the complex utilization of all available forces and means. Tracking facilities at present included in the equipment of surface vessels allow search and pursuit of enemy submarines to be conducted with great effectiveness. When surface ships are equipped with antiaircraft missiles and helicopters, their potential in combatting submarines will become even greater. Such an appraisal of the role of surface vessels in combatting enemy submarines is dependent on their ability to remain at sea for long periods of time at a considerable distance from land and to reconnoiter large areas of the sea in short periods of time with the help of helicopters.

The dispersed basing of the naval forces, the use of dispersed antiatomic combat and transit formations, the constant threat from enemy aircraft, submarines, and mines all stipulate the need to give

cover to submarines not only when entering or leaving their bases, but also to cover their deployment for operations in the open sea. Such support will take the form of combat with the antisubmarine submarines of the enemy which are deployed at the points of emergence of our submarines - in the narrows as well as along their probable routes to the open sea - and the detection and destruction of mines along the route of passage. Although the antisubmarine submarines and aircraft will be able to conduct combat with enemy submarines, surface vessels will play an important role in this engagement under cover of antiaircraft missile units of the Navy and the Antiaircraft Defense of the Country. As far as the danger from mines is concerned, it will be effectively conducted both now and in the near future only by surface vessels /part of line missing/... forces of the Navy, it will be necessary to bring in our missile-equipped surface vessels to engage with those enemy surface vessels which are interfering with the deployment of our submarines; for use as protection for vessels of antisubmarine defense, which are engaged in searching for enemy submarines at a considerable distance from shore, and for dealing with the destruction of enemy landing craft and their support ships.

In a future war a significant role in support of ground troop operations will be the providing of sea transport of men and materiel, mounting tactical landing operations and disrupting naval communications between the enemy's coastal groupings and his rear bases. For the solution of these missions it will be necessary to use, along with other forces, surface vessels of small displacement. Only surface vessels of various designation will be able to accomplish such missions as protecting the transport of troops and military equipment, heavy freight, and troop landings.

It will be up to surface vessels equipped with antiaircraft missiles to screen convoys and transports from aerial attack during their passage and in many cases the vessels at their bases.

Surface vessels will have a definite role in the laying of antisubmarine and antilanding minefields.

Such are the basic missions which require the use of surface vessels. It is obvious that complete solution of these missions cannot be accomplished by conventionally armed ships. New classes of vessels with modern weapons will be required.

The composition of the Navy must include special vessels of two basic classes for antisubmarine warfare against enemy submarines;

vessels for short-range operations, and vessels for long-range operation. Both classes must have modern hdro-acoustical equipment, powerful antisubmarine weapons, antiaircraft missile weapons, and antisubmarine helicopters. With such aids they will be able to carry out long-range searches and destroy enemy submarines.

Special vessels such as trawlers, landing craft, and transports will be needed for locating and destroying mines, and transport of landing parties, troops, and equipment.

Vessels equipped with missiles will cover antisubmarine defense (PLO) vessels against attack by enemy surface vessels, primarily from carrier-borne hunter-killer groups of PLO forces, and will escort convoys and landing parties during their ocean passage.

Antiaircraft defense vessels will be needed to screen PLO vessels, convoys, and landing parties during the sea passage and in many cases to protect the bases of submarines and other combat vessels against air attack.

The conditions of the use of surface vessels of various types at the present time are characterized first of all by the fact that it became more difficult for them to defend themselves against enemy air attacks than previously. Aircraft carrying missiles can use their weapons against surface vessels from distances of much greater range than antiaircraft missiles launched from vessels. For this reason surface vessels have practically lost the capacity to defend themselves against air attack and are faced with the necessity of countering airborne missiles of great speeds, equipped with homing guidance and powerful nuclear charges, and having a high probability of hits.

Missile-equipped submarines will present, together with aircraft, a great menace to surface vessels. Missiles launched by these submarines, having the same characteristics as those launched by aircraft, will be able to strike at surface ships under any weather conditions. Fitting missiles with nuclear charges significantly increases the possibility of destroying surface vessels at the time when the vessels will have only a limited opportunity of defense against this weapon.

A particularly dangerous enemy of present-day surface vessels are nuclear-powered submarines equipped with long-range homing torpedoes and missiles capable of carrying nuclear charges. Nuclear submarines, capable of a high degree of concealment, have a speed about equip to that of the fast-moving surface vessels. In addition,

submarines have an advantage over surface vessels in the use of hydroacoustics. A surface vessel can be spotted from a submarine at a much greater range than a submarine from a surface vessel. Because of this, submarines are able to successfully attack surface vessels before being spotted, and can use their weapons more effectively than the surface vessels under attack by submarines. Nowadays submarines will not always strive to avoid encounter with surface vessels but will sometimes even attack PLO vessels.

In many cases, the present-day surface vessels will not be able to emerge victorious from an engagement with submarines. Though if still capable of carrying out independent combat against conventional diesel submarines, their capacity to effectively search, pursue, and destroy, or sometimes even to escape from nuclear submarines, is very limited. These circumstances made it necessary to equip surface vessels with antisubmarine defense helicopters which may help to make up the deficiencies of surface vessels in their combat against missile-equipped nuclear submarines.

The potentialities of the mine as a weapon against surface vessels have also substantially increased. The present day reaction-surfacing (reaktivno-vsplyvayushchiy) mines are equipped with extremely sensitive non-contact detonators; these are based on the principle of exploitation of various physical fields of the vessel, and are adapted for installation within a wide range of depths. These properties make for a considerable increase of the areas considered hazardous for surface vessels. Conducting combat with mines in a theater of operations will take much effort and various combat means will have to be used. This will also limit the possibilities of the use of surface vessels for the solution of combat missions.

The future saturation of all arms of the naval forces with radio-electronic devices, will create conditions which make it impossible for surface vessels to conceal movement, even under the most advantageous weather conditions. Surface vessels can be detected by modern reconnaissance means at any time of day or night and in any part of the operational theater, and are subject to strikes by nuclear/missile weapons whose effectiveness is also independent of the time of day or night, or of weather conditions.

The threat of enemy use of nuclear weapons forces surface vessels to sail in dispersed formations. At the same time, due to the increase in the firing range of submarines, escort vessels must be placed at much greater distance from the escorted forces than in the

[redacted]

1.3(a)(4)

past. In order to create the necessary conditions for surface vessels for their solution of combat missions, it will be necessary to increase considerably the number of escort vessels which will have to be placed along the increased perimeter of the defended area. Practically speaking, however, in an overwhelming majority of cases this will be impossible.

While submarines use cruise missiles against escort vessels and transports, antisubmarine defense vessels will be able at best to use only their antiaircraft missiles. They will not always be able to take direct action against the submarine itself.

The use of improved homing devices will effectively increase the possibilities of destruction of surface vessels by torpedoes launched from submarines and small surface carriers.

The development of radar and the increase in the maximum effective range of coastal defense weapons in large measure impedes the approach by surface vessels, even in a distant approach route to the enemy coast. It has become increasingly difficult to use large vessels in confined theaters of operation; they can be detected by the enemy directly during their departure from their bases. Therefore, in order to utilize surface vessels effectively for the solution of combat missions in the enemy's coastal area, particularly in confined theaters of operations, a set of complex measures for their security will be required.

All of this complicates to a marked degree the utilization of surface vessels, and requires a large expenditure of forces for the support of their operations.

However, surface vessels which have missiles of various types, and radioelectronic apparatus, increase the combat capabilities of their individual classes. Today even small vessels equipped with missiles are capable of combat with large vessels carrying a greater number of missiles. In addition, the vessels' armor and other means of protection against nuclear weapons will have practically no bearing on the outcome of a combat encounter. This entails the complete rejection of a centuries-old principle which maintained that surface vessels can be used only in combat against similar or "equivalent strength" (ravnoznachnyy) vessels. Any vessel, although equipped with the most powerful modern weapons, heavy armor and perfect means of defense, can be destroyed by even a patrol boat capable of launching missiles. More than that, vessels of small displacement

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

which are not easily detected by radar and which, for this reason can approach a large vessel to within the range of their missiles, will possess important tactical advantages over the enemy.

The vessles of a striking force equipped with missiles, will not have to execute a complicated maneuver in order to take and hold positions adjusted in relation to the enemy, in order to use their weapons. Approaching and holding the firing position will also depend to a lesser degree on the relative speeds of the vessels engaged in combat, and their relative disposition.

Equipping vessels with antiaircraft missiles will lessen their dependence on constant air cover provided by land-based fighter aircraft, will permit them to resolve missions outside coastal zones of the PVO and to defend themselves from the means of enemy air attack. However, the restricted supply of antiaircraft missiles always will be the reason for the ship's limited time at sea.

In orgsnizing tactical coordination between separate tactical groups of surface vessels, as well as between vessels and aircraft, it will not be necessary to maintain the rigidly prescribed disposition of tactical groups in relation to each other and to the chosen grouping of the enemy. In order to inflict a coordinated, concentrated strike against the enemy, it will be sufficient to have only the exact target designations and a predetermined sequence in the use of weapons by the various tactical groups. Therefore there are wider possibilities of organizing tactical coordination of surface vessels with aircraft in the solution of combat naval actions, in which case the control and guidance of the striking groups of aircraft could be effected from the surface vessels.

The diversity of the missions assigned to surface vessels and the extensiveness of the areas in which armed combat at sea will unfold, dictate the necessity of intensive use of surface vessels throughout the course of the entire war. Furthermore, the intensity of these military operations will vary. It will be highest during the initial phase of the war, and also while supporting the deployment of large forces of submarines for operations at sea, and during their return to bases in the later phases of the war. It will also be augmented considerable while enemy submarines are in action against our naval forces and coastal installations.

In this connection it is important to plan surface vessel operations meticulously and ahead of time and to have the vessels so

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

located that they initiate the solution of combat missions immediately upon the outbreak of war. This is particularly true for vessels assigned to operate against enemy missile-carrying submarines and of missile vessels brought in for protection of operations by PLO vessels.

The distribution of effort, as well as the content of the tasks being resolved by surface vessels, will depend in large measure on the nature of the theater of operations and of the anticipated operations of the enemy.

In open theaters of operations the basic content of combat operations by surface vessels will be the screening of submarines during their deployment, and engaging in combat with enemy missile-carrying submarines. A significant part of the surface vessels' efforts will be expended in supporting the passage of convoys.

In confined theaters of operations, surface vessels will perform a limited number of tasks, the basic ones being the defense of naval bases and operations against the enemy's lines of communication.

The qualitative composition of surface vessels in a fleet depends on the nature of the theater of operations. The basic composition of the fleet's surface vessels operating in open theaters of operations, will consist of antisubmarine defense vessels with a wide radius of operation, antiaircraft defense vessels, and missile vessels. In confined theaters of operations, precedence will be given to small PLO vessels, missile patrol boats and small missile vessels. [1]

Let us now examine the methods of combat use of surface vessels in the solution of specific combat missions.

The use of surface vessels to support the deployment of submarines, as stated above, will be more characteristic of open theaters of operation. Surface vessels of various types will have an important role in the solution of this task, especially in their coastal zone, where their basic efforts will be required to be concentrated on the conduct of combat with enemy submarines, and on removing the threat of mines along the routes of deployment of our submarines. Combat operations of surface vessels will be conducted simultaneously with operations of antisubmarine aircraft and helicopters, using at the same time various positional resources of the PLO.

---

1. For some time, motor-torpedo boats equipped with long-range homing torpedoes will continue to be of value.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The basic classes of vessels brought in for operations in coastal waters, will be antisubmarine vessels of short operational range which will be used in tactical coordination with other arms of naval forces, and ships of antimine defense (PMO).

As the submarines being deployed get further away from their bases, the composition and the nature of operations of the enemy's forces in action against our submarines will change and, therefore, there will also be a change in the composition and operations of our forces supporting the deployment. In distant theaters of operations, the basic threat to submarines will come from antisubmarine submarines, carrier-borne hunter-killer groups (APUG-avianosnaya poiskovo-udarnaya gruppa) and antisubmarine aircraft of the enemy. In these areas, in contrast with the coastal zone, it will be necessary to conduct combat not only with the enemy's submarine and air forces, but also with his surface vessels - specifically, the APUG. In this connection, it is imperative to give the antisubmarine hunter-killer groups anti-aircraft support by assigning a certain number of PVO vessels to them, and by bringing in missile vessels to screen the groups.

During the conduct of combat against enemy antisubmarine defense forces in the zone of deployment of submarines, the surface vessels must operate in tactical groups whose number and composition must be such as to ensure the solution of the main mission.

Operations of tactical groups of surface vessels in distant areas are carried out in close coordination with antisubmarine aircraft and antisubmarine submarines, and are supported by missile-vessels and attack aircraft, and, whenever necessary, by units of missile troops.

Missile vessels will primarily be used by independent tactical groups operating in the zone of movement of our submarines, or in the maneuvering area of our surface force grouping which is carrying out search and destruction of the enemy's antisubmarine submarines.

The operations of our antisubmarine vessels supporting the deployment of submarines will result in the detection, destruction, or forced withdrawal of the enemy antisubmarine submarines found in the zone of movement of our submarines to a distance exceeding the range of their weapons. These operations will be planned according to the usual tactics of the hunter-killer groups used for the detection and destruction of the enemy antisubmarine submarines.

In order to limit the possibility of undetected penetration by

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

enemy antisubmarine submarines into the secure area in order to attack our submarines, the operations of the vessel hunter-killer groups will have to be supplemented by specially detailed vessels which would set up screens of sonar (radiogidro-akusticheskiy) buoys on the borders of the zone under observation. The operation of these screens, set up at a short distance from the coast, will be by antisubmarine aircraft and vessels, as well as by helicopters based on the coast. At a great distance from our coast, this operation would be done by some of the helicopters carried by antisubmarine vessels, as well as by vessels and aircraft. Enemy submarines detected by the sonar buoys must be attacked and destroyed by the vessels, aircraft, and helicopters detailed for operations in that area.

During support of submarine deployment, simultaneously with the solution of missions of combat against enemy antisubmarine forces, there will have to be a search for and destruction of mines laid along the line of passage of the submarines. Trawlers and helicopters can be used for this purpose. Special groups must be formed from these, capable of destroying mines in those areas which cannot be bypassed by the submarines.

The use of surface vessels in combat against enemy missile submarines will consist of the search and destruction of those submarines, mainly within the boundaries of the possible firing positions for submarines approaching the coast to strike targets situated in the depth of our territory. The use of surface vessels in the outer zone of antisubmarine defense will be limited because of the difficulty in the matter of their support.

Taking into account the disposition of a series of objectives and the capabilities of enemy missile submarines, one can assume that the probable areas of their firing positions will be 300-900 miles (540-1600 kms) from the coast. In these areas, combat against enemy submarines will be carried out primarily by long-range antisubmarine vessels resolving missions in coordination with antisubmarine aircraft and submarines, utilizing the systems of antisubmarine surveillance available in the theater of operations.

In open areas, surface vessels can resolve the missions of location and destruction of enemy submarines only if they use the data on the initial discovery of these submarines obtained by the positional resources, aircraft, and helicopters. The operations of the antisubmarine vessels must be organized in conjunction with the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

operations and disposition of these capabilities.

Unilateral operations by surface vessels in locating enemy missile submarines in open areas will be extremely ineffective, since missile submarines, having a hydroacoustical detection system of wider range than surface vessels and the capability of the same speed, can avoid any encounters. In addition to this, having weapons with an effective firing range equal to the range of detection of the surface vessels, the submarines can destroy them before they themselves are detected.

In this connection, and considering the present capabilities of surface vessels in combat with atomic submarines, which maneuver over wide areas, the former can be counted upon as a real force only if they operate within a unified system of antisubmarine defense for a given theater of operations, as one of its components.

Surface vessels can successfully conduct unilateral combat operations against nuclear submarines when the latter are trying to break through narrows, when the possibility of dispatching forces for detection purposes can realistically be expected to meet with the necessary success, and when the enemy submarines must operate within a limited area.

Inasmuch as the length of stay at sea of the tactical groups of vessels of the PLO is insignificant, due to the limited supply of antiaircraft missiles on their escort vessels, they will for the time being be able to go out into distant areas only periodically, for resolving missions of locating and destroying those enemy missile submarines which have been detected through other means within the limits of the sea zone of antisubmarine defense. As antisubmarine defense vessels are equipped with an increased number of antiaircraft missiles and as more antiaircraft defense vessels join their ranks, their use for operations in distant areas for continuous long periods of time will be increased.

On the whole, the operations of surface vessels far removed from their coast will have an important bearing on the general system of combat with enemy missile submarines. Their use in those areas will increase significantly the effectiveness of antisubmarine defense, and will become a substantial addition to the operations of anti-submarine submarines and antisubmarine defense aircraft.

In the coastal zone (pribrezhnaya zona), small surface vessels

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

of PLO will be used to good advantage for locating and destroying enemy submarines. They will fulfil their missions in coordination with aircraft of the antisubmarine defense and shore-based helicopters, and will be supported by a wide-range (razvernvtyy) observation system consisting of various forms of fixed resources.

Operations of the forces of antisubmarine defense in the near zone (blizhnaya zona), in polar areas, and at the edge of ice, will be conducted systematically.

The joint search for enemy submarines by antisubmarine vessels and helicopters can be carried out within the borders of the coastal zone of the PLO by using land-based helicopters. In the Arctic the range of combined operations by vessels and helicopters can be somewhat increased by setting up helicopter bases on the ice.

It is necessary to use helicopter-carrying vessels for locating submarines in distant and open water areas. However, since helicopters have a limited load-lifting capacity and range of operations, they can be fitted only with equipment for finding submarines within a comparatively short range from the parent vessels. As for the destruction of submarines, the solution of this task presents well-known difficulties for helicopters, since they are incapable of carrying the necessary torpedoes or bombs. For this reason, it will be necessary in the near future to use helicopters together with antisubmarine vessels which are capable of carrying large supplies of submarine destruction weapons for long periods of time.

The hunt for enemy submarines can be carried out by groups of surface vessels with special equipment enabling them to detect the position of a submarine by the column of ionized gases at the moment of launching of the ballistic missile. These vessels must have long range antisubmarine missiles in order to be able to destroy the submarine. The groups of vessels set aside for a hunt by the method stated will be deployed in the areas assigned to them in such a way that they can effect an overlap of detection along the entire zone of possible firing positions of the enemy submarines. The distance between groups of vessels must be such that a detected submarine can be destroyed by antisubmarine missiles at any point of the observed area. The operations of vessels conducting a submarine hunt based on detection of the column of ionized exhaust gases of the missiles will be carried on in coordination with shore installations established for the same purpose.

The hunt for enemy missile submarines by ships of the PLO can

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

be carried on with the aid of the fixed hydroacoustical observation systems or with sonar buoys set out by vessels and aircraft. Surface vessels, utilizing the information on detected submarines as it comes in through the fixed hydroacoustical means of detection, can then go to the area where the submarines have been detected, and locate and pursue them.

In coastal zone operations, surface vessels can execute the hunt when called upon on the basis of primary data received from the fixed hydroacoustical systems of submarine detection. In addition, surface vessels can be used for patrol searches (kontrolnyy poisk) of those submarines which have penetrated into the coastal zone.

In solving missions concerning the defense of naval communication lines, surface vessels will be used for the protection of moving convoys against attacks from submarines, aircraft, surface vessels, and mines. Various classes of surface vessels will constitute the basis of naval forces assigned to defend communication lines. This is due to their ability to stay at sea for long periods of time, their readiness to repel enemy attacks under difficult weather conditions and their acceptance of a significant part of the effort in carrying out antisubmarine, antiaircraft, and antimine defense of convoys during their sea passage.

Surface vessels assigned for antisubmarine, antiaircraft, and antimine defense will resolve their missions primarily by the method of direct defense of the transports.

The antisubmarine defense of the convoys must be so arranged as to secure their defense from both porpedoes and missile weapons from submarines.

The antiaircraft defense of the convoys in coastal areas, must be effected by the troops of PVO of the Country, aided by vessels of antiaircraft defense. There will be a special need for the use of PVO antiaircraft vessels in the next few years for the protection of convoys moving beyond the areas of responsibility of the troops of PVO of the Country.

The convoys will be able to move away from the coast only in the company of PVO vessels carrying powerful antiaircraft missile weapons. In this connection, the duration of their movement outside the zone of responsibility of the troops of PVO of the Country will depend primarily on the presence of PVO vessels within the composition of the convoys, and on the number of antiaircraft missiles which can

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

be used for repelling air attacks.

In operations beyond the coastal zone of PVO, the PVO vessels will be included for the most part in the composition of the convoys, included in the general combat formations with them.

In many cases the PVO vessels, jointly with other PVO forces and resources in a common plan, will be used for defense of the basing and assembly points of the convoys. Specifically, they can be used for radar surveillance in a naval sector, as well as for reinforcing units of troops of PVO of the Country which protect installations of the Navy. This will permit a considerable increase in the depth of the PVO points of basing and communication lines within a naval sector. In newly created basing points where fixed PVO means have not yet been deployed, PVO vessels might be the only means of combatting the enemy in the air.

In open theaters of operations missile vessels will have to be detailed for screening convoys against possible strikes by enemy surface vessels, inasmuch as the convoys make their long distance passages slowly and at a considerable distance from shore. These vessels can be merged into independent groups. When multi-purpose missile vessels are used to reinforce the PVO of convoys part of them can proceed in the same formation with the transports.

In confined theaters of operations, missile vessels will not be used as often for screening the convoys, since this mission can be resolved for the main part by missile troops and naval aviation.

The use of surface vessels in antimine defense will consist of the detection and destruction of mines in the areas of bases and of operations of submarines and surface vessels, as well as along the routes of convoys. Inshore the search for mines will be carried out by search vessels (korabl-iskatel), jointly with the coastal and sea-going resources of PMO. In areas far removed from the coast, this mission can be resolved only by means of vessels.

In their search for mines in coastal areas where the places of mine-laying are determined by shore-based or floating posts of anti-mine detection, the search vessels must move into the places indicated by these posts, and conduct a search for the mines. The destruction of the mines located will be done by special vessels guided by the search vessels.

The use of surface vessels in support of ground troops will

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

depend on the missions being performed by the latter. Surface vessels can be used for landing operations and for the protection of flanks and certain installations in the rear of a maritime front, against operations of enemy missile vessels, including patrol boats.

In landing operations the basic mission of surface vessels consists of the transportation and unloading of heavy equipment in the landing sector. This mission is resolved by special landing craft whose operations are supported by missile vessels and vessels of the PLO, PVO, and PMO. The operations of the PVO vessels have an especially important role. As they follow the overall route and combat formations of the landing craft, they give cover from air strikes to the landing parties during sea passage, during the landing operation, and subsequently, until the deployment of antiaircraft missile units on shore; they will also protect the actual points of landing.

Missile vessels, especially patrol boats (kater), will be used extensively to cover the landing force during their transport at sea, from enemy missile vessels. In many cases these vessels can be merged into detachments of fire support vessels (OKOP - otryad korablay ognevoy podderzhki) assigned specific targets on shore, in the interests of the support of the landing operations.

Missile vessels and patrol boats will play an important role in the resolution of missions for the destruction of coastal communication lines serving the enemy's maritime groupings of troops. In addition, missile vessels can be used for the destruction of enemy surface vessels supporting ground troops which are situated outside the range of fire of the coastal, short-range missile complexes.

In resolving missions for the support of troops carrying out a defensive action on shore, missile vessels, especially patrol boats, will participate in the destruction of enemy vessels and landing force transports as they approach the defended coast; they will also participate in the destruction of the vessels protecting the enemy's landing operations, above all the PVO and PLO vessels.

The operations of missile vessels covering the troops on shore who are on the defensive against the enemy strikes from the sea are carried out in coordination with units of missile troops of the Navy. They will consist mainly of periodical patrolling by groups of vessels close inshore in order to detect and destroy enemy missile vessels attempting to penetrate areas not monitored by units of the missile troops of the Navy.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

.....

The use of nuclear/missile weapons has had its direct effect on the development of such arms of naval forces as surface vessels. Having lost their role as the basic naval striking force, surface vessels have become an integral part of the support forces and have retained the capacity to resolve certain other missions.

Equipping surface vessels with cruise and antiaircraft missiles, with modern means of antisubmarine defense and installing new engines-steam-turbine and nuclear-will permit a wider use of surface vessels. New surface vessels will be able to stay away from their bases for a long period of time and, operating at a significantly long range from their coast, they will be able to perform various important combat missions.

In a future war, the use of surface vessels of various classes in coordination with other arms of the naval forces will give reliable support to submarine operations and will result in the more effective performance of combat missions against missile submarines of the enemy, as well as a more successful defense of the basing areas of naval forces.

The Utilization of the Forces of the Navy

in a Missile/Nuclear War

by

Rear-Admiral V. Lisyutin

Each type of armed forces has its strong and weak aspects. By combining the strong sides of the different types of armed forces, combat missions can be accomplished in the most effective way under various conditions. There cannot be an absolute weapon, capable of accomplishing every mission in the most effective way under all possible conditions. For this reason the different types of our armed forces are developed according to their combat characteristics and capacity to accomplish the main missions in a war in a concrete historical situation.

One of the main strategic missions in contemporary warfare is the disorganization of the enemy's economy. It is accomplished mainly by missile troops of strategic designation who can take action successfully against stationary economic targets, most of which are known in advance. However, besides the latter, there are also mobile economic objectives, in particular transport ships. It is known that the aggressive capitalist countries have at their disposal about 80 million registered tons of dry cargo-carrying tonnage and more than 20 million registered tons of tankers. It can be surmised, naturally, that the probable enemy, preparing to launch a missile/nuclear war, could have all this tonnage fully loaded in advance and under way at sea or dispersed far away from large economic centers. The economic supplies on these mobile objectives are very considerable and could have a big influence on the course of armed combat, especially in its initial period. Missile troops of strategic designation cannot yet strike at such mobile objectives effectively. This is a mission for aviation and the Navy.

[redacted] 1.3(a)(4)

Another most important mission facing the armed forces - the destruction of the enemy's means of nuclear attack - is even more complicated as, besides the fact that most of these means will be dispersed, under cover and camouflaged, a considerable part of them will prove to be, at the beginning of a war, not on land, but on the seas and oceans carried on mobile means - aircraft carriers, missile carriers, submarines and in maneuvering supply detachments (manevrennyy otryad snabzheniya).

If one calculates, on the basis of the norms adopted in the United States Navy for supplying vessles with nuclear weapons, intended for operations against shore and sea objectives, then it will turn out that not less than 5 or 6 percent of all available nuclear warheads will be concentrated on vessels. In the seagoing supply bases there will also be not less than one complete unit of fire, so that altogether at the beginning of a war, vessels and supply ships may be carrying up to 10 to 12 percent of all the probable enemy's available nuclear warheads, which cannot be attacked by surface-to-surface (nazemnyy) ballistic missiles, but must be destroyed by the forces of the Navy. Thus, a considerable part of the second basic mission - destruction of the enemy's mobile nuclear means of attack - must also be accomplished by the Navy in cooperation with aviation.

In comparison with other types of armed forces, the Navy has very important combat characteristics and possibilities peculiar to itself. These possibilities are considerably enhanced by the introduction of missile/nuclear weapons and atomic power plants in vessels.

In conditions of a sudden outbreak of a missile/nuclear war, the Navy has greater combat stability than the other types of armed forces, owing to the possibility of being at dispersed bases on a long stretch of coastline, and also of being able to put to sea in advance. Dispersed naval forces will not present an attractive target to an enemy for strikes by the

[redacted] 1.3(a)(4)

enemy's multi-megaton nuclear charges (zaryad), the use of which is most likely at the beginning of a war, at the time when the large units of other types of armed forces, though dispersed over large areas, can be subjected to great destruction as a result of such strikes.

If the problem of withdrawing these or other forces from the enemy's first missile/nuclear strikes has not been solved successfully, their employment in the war is very problematical. The possible dispersion of and partial cover for such forces will not enable them to avoid losses, and consequently, to retain their full combat effectiveness. Even the most mobile type of armed forces - aviation, which, under certain conditions can be withdrawn directly from a strike, will, if deprived of airfields, lose its combat effectiveness to a considerable extent. On the other hand, naval forces deployed at sea, with their main arm - submarines, cruising submerged, can be withdrawn most successfully from a strike, and can, therefore, be used with full combat effectiveness during the first strikes at the enemy.

The most important quality, peculiar to the Navy, is its ability to deliver powerful strikes at moving objectives at sea. The forces of the Navy, armed with modern missile/nuclear weapons, possess a high degree of operational-combat capacity. Thus, the operational-strategic exercise conducted by the Commander-in-Chief of the Navy in August 1960 showed that even one submarine with an atomic power plant can make repeated attacks on a carrier strike large unit at sea and destroy one or two large vessels. A brigade of such submarines can successfully accomplish the mission of destroying a carrier strike large unit consisting of several aircraft carriers and operating in a definite direction occupying, along the front /two or three words missing/. The destruction of a carrier strike large unit carrying 100-120 nuclear warheads means that the enemy is deprived of these nuclear warheads for use against our installations.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

If one considers the possibility of repeated employment of the carrier strike large units, then their destruction will save us from many hundreds and even thousands of nuclear strikes.

In the near future the United States will have up to 40 atomic submarines, armed with 16, and possibly more, "Polaris" type ballistic missiles with nuclear warheads. In the course of one cruise these submarines will be able to use up to 640 and more nuclear warheads against our installations, and if resupplied twice at sea - up to 2,000 nuclear warheads. It is mainly the Navy that can conduct combat against such submarines.

The arming of our submarines with ballistic missiles with nuclear warheads makes them a very effective weapons in the accomplishment of the mission of disorganizing the enemy's economy and destroying his means of nuclear attack. It is true that in some respects submarines armed with ballistic missiles are inferior to surface-to-surface ballistic missile installations (lower accuracy of fire, reduced readiness in view of the necessity to deploy and take up firing positions, etc.), but they also have important advantages.

While surface-to-surface missile installations cannot fire a significant number of salvos in present-day conditions from the same position without suffering retaliatory action, a submarine, especially in launching missiles when submerged, can successfully make use of its whole unit of fire of missiles from one position, remaining under way all the time.

Possessing high maneuverability and concealment, a missile-carrying submarine will, in the initial period of war, prove to be the least vulnerable and most stable combat means, capable of delivering sudden and powerful nuclear strikes in important directions.

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

In modern conditions all ground means are vulnerable to effective action from enemy nuclear weapons. Moreover, if they are not destroyed, they will be in the zone of radioactive contamination, which will reduce considerably their combat effectiveness. On the other hand, a missile-carrying submarine, being under water, is not vulnerable to radioactive contamination, and can always bypass dangerous zones.

Missile-carrying submarines, being least vulnerable to a sudden missile/nuclear attack by the enemy, can become a special weapon in the hands of the Supreme High Command. It is not mandatory to use them immediately on the outbreak of a war; they can be held in reserve for accomplishing missions directed toward the successful completion of the initial period of war. With the possibility of resupplying missile-carrying submarines at sea, use can be made of them repeatedly (both at the very beginning of a war, as well as during its initial period and subsequently).

Thus, the Navy possesses important operational-combat capabilities and advantageously complements the missile troops of strategic designation in the accomplishment of the most important strategic missions with which the armed forces are faced. However, the methods of using these capabilities of the Navy and the methods of conducting naval operations require, in our opinion, further serious elaboration.

Even during the most important exercises and games, we have hitherto, in essence, considered the operations of the Navy only at the very outbreak of a war, and not during the whole of its initial period, which has afforded possibility for studying only questions connected with delivering the first strike. It is essential to work out the complete accomplishment of the basic missions during the initial period of a war, and foremost in the theoretical field.

Let us examine, briefly, the main missions of the Navy, the possible conditions, and the methods for their accomplishment.

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The destruction of the strike forces of the enemy's Navy, including strike aircraft carriers, missile-carrying vessels, and, in the near future, atomic submarine missile carriers, is one of the priority tasks of the Navy.

At the beginning of a war the probable enemy is able to deploy up to seven carrier strike large units (AUS), each consisting on the average of three aircraft carriers, three cruisers armed with missiles, and 12 to 18 destroyers, armed partly with antiaircraft missiles. It is most probable that these carrier strike large units will be distributed in theaters in the following way: North Atlantic - 3, Pacific Ocean - 2, Mediterranean Sea and Indian Ocean - 1 each.

Combat with carrier strike large units must be conducted in three directions; destruction of the AUS themselves, destruction of their mobile supply detachments at sea, and destruction of the naval bases at which they are based.

The destruction of the AUS at sea (in the ocean) must be the main mission of submarines, missile aviation, of the Navy and long-range aviation. The destruction of mobile supply detachments at sea, insofar as they are beyond the range of aircraft, will be the mission of submarines. Finally, the destruction of the bases of carrier strike large units (including the shore bases of carrier aircraft) must be accomplished by missile troops of strategic designation. The use of missile-carrying submarines for the latter mission is also not excluded.

Taking into account the striving of the probable enemy to unleash a war suddenly, it may be expected that at its outbreak all strike aircraft carrier and missile-carrier large units will not be at bases, but at sea, at the takeoff lines of deck-based aircraft for strikes. So long as the AUS remain beyond these lines before the beginning of military operations, there would in most cases be no grounds for action against

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

them before they approach these lines. Consequently, our forces should be deployed on the probable lines where the enemy's deckbased aircraft will take off. Here, too, should be concentrated the main efforts of atomic and diesel-battery submarines and missile aircraft using nuclear weapons, for the most part.

The complications involved in deploying forces when repelling a sudden nuclear strike by the enemy at the outbreak of a war, and the striving to employ strike aircraft carriers in accordance with the principle of swift approach, strike, and rapid withdrawal, cannot always create conditions for the complete destruction of carrier strike large units with the first strike, which will require continuation of operations until the mission is fully completed. In such circumstances, missile aircraft, after reloading, prepare for a repeated strike at the AUS when the latter makes a new attempt to approach the line for launching deckbased aircrat, while atomic submarines pursue the enemy and inflict repeated blows on him. An especially advantageous time for such strikes will be the period when the vessels are being resupplied and refueled by the mobile supply detachments, which must also be objectives for strikes by atomic submarines.

At the beginning of combat operations, diesel-battery submarines, disregarding the lines of takeoff for deckbased aircraft, should move farther ahead with a view to inflicting preventive strikes on aircraft carriers before the carriers repeat their approach to the line of takeoff for deckbased aircraft. Naturally, after the beginning of combat operations, the lines where the main efforts are to be concentrated should be selected with a view to delivering strikes on the AUS before they approach to within range of deckbased aircraft. Atomic submarines, making use of their great maneuverability, can deliver strikes on AUS in the ocean wherever they overtake them.

Such can be the general scheme for the complete accomplishment of the mission of destroying each AUS.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Combat with missile-carrying submarines which, on the outbreak of war, will also be deployed in lines from which missiles can be launched, should take form from operations for the destruction of the submarines themselves, their shore bases, and their mobile supply bases at sea.

The most probable areas of deployment of missile-carrying submarines will be the Northern Arctic Zone and the Norwegian Sea, which open up the shortest route to targets which are in the depth of our country, and are for that reason least accessible to the enemy's main carrier of nuclear weapons - aircraft (hence the most important strategic significance of combat with missile-carrying submarines, especially in the Northern Arctic Zone). This is fully confirmed by a study of the operations of United States atomic submarines mainly in the Northern Arctic Zone. At the same time, the possibility of operations by missile-carrying submarines from other important directions is not excluded.

According to the system adopted in the United States for the distribution of targets among the different types of armed forces, targets for the Navy are situated at a depth of up to 1,000 kms from the coast. Taking the maximum range of fire of submarines with ballistic missiles of the "Polaris" type as 2,800 kms, the main efforts against submarines in the initial period of a war must be concentrated on the lines from which they would launch their missiles, i.e., at a distance of 1,800 kms and more (1,000 miles) from the coast.

The main forces that will be involved in accomplishing the mission of destroying submarines in distant areas will be submarines, antisubmarine aircraft, and antisubmarine vessels. As positional means of detecting and destroying submarines cannot be set up in peacetime in neutral waters, reliance should not be placed on their wide use in the initial period of a war.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Maneuvering antisubmarine forces could be concentrated without hindrance before the beginning of combat operations on the lines of operations of missile-carrying submarines, and after detecting the submarines they could maintain hydroacoustic contact with them until an order for using weapons is received or until they make their first attempt to launch missiles.

Accomplishing the mission of detecting submarines in the extensive areas of seas and oceans demands an excessively large expenditure of existing forces and weapons, which calls for the creation of new means permitting the surveillance of extensive water areas in short periods of time. In this respect, the greatest capabilities are possessed by long-range seaplanes making use of small sonar buoys, and also by antisubmarine vessels carrying antisubmarine helicopters. Armed with antiaircraft missiles, surface antisubmarine vessels could considerably extend their zone of operations.

Combat against missile-carrying submarines can be conducted most successfully by antisubmarine submarines in all conditions, especially in areas of pack and drifting ice. In areas of clear water and broken ice, use can be made to some extent of antisubmarine aircraft and helicopters. An automated system of lines of radio-hydroacoustic stations and cable-hydrophone lines set up on the ice can significantly facilitate the detection of submarines in conditions of ice.

The destruction in the ocean of mobile supply bases for missile-carrying submarines should be carried out by our submarines operating against the mobile supply detachments of carrier strike large units or by specially allocated submarines, if the areas of operations of the missile-carrying submarines and the AUS of the enemy do not coincide.

The destruction of the stationary bases of submarines, as well as of the bases of carrier strike large units, must be accomplished by the missile troops of strategic designation.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Submarines have now become the principal striking force at sea. In accordance with this, combat against them must inevitably change from being a type of defense to the basic offensive mission of the Navy in destroying the enemy's forces at sea. Combat at sea is going under water. Forces operating against submarines will eventually become the basic strike forces of the Navy.

The existing antisubmarine forces and weapons of the Navy, with the exception of submarines, can in fact carry on combat with enemy submarines only in the coastal zone. This is far from adequate. Antisubmarine forces, as the basic means of combat against the future main strike forces of the enemy Navy, have a great future, and special attention must be paid to their development.

Combat against missile-carrying submarines presents a new problem. Ways of solving it are still under investigation. It is possible that in the future they will turn to some extent into combat between "two of a kind" (between submarines) under water.

The probable enemy, intending to carry on an aggressive war against the countries of the Socialist Camp across the ocean and not relying on holding the bridgeheads now occupied by him on the Eurasian continent, will inevitably attempt to make major landings in order to seize new bridgeheads or to reestablish the situation on them, and also to undertake sea shipping in order to supply the groupings established in these areas. In this connection the question arises: where, how. and with what forces can combat with landing forces (and also with convoys on communication lines) of the enemy be conducted most effectively?

The view is expressed that: "Enemy landing operations, while enroute at sea, do not merit expensive and cumbersome operations against them by the Navy and long-range aviation. The basis of their annihilation can be by missile strikes

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

in embarkation and debarkation areas; while enroute at sea, it is again more expedient to annihilate landing forces by strikes with missiles having nuclear charges of several megatons".[1]

There are, of course, many ways in which any mission can be accomplished. In selecting them, the aim should be to accomplish each mission as quickly as possible, using the minimum forces and suffering the smallest losses. In a more detailed examination of the questions of combat against enemy landing forces, we come up against the following circumstances which militate against accomplishing the mission in the way outlined above.

A landing force at embarkation ports cannot as yet be an objective for missiles with nuclear and, even less, with conventional warheads. As experience in the Second World War has shown, landing detachments are formed at many ports which are not even situated on the same continents (Sicilian and Normandy landing operations, landings in northwest Africa, etc.). At present the enemy is working toward a system of operational and combat training of embarking landing troops where there are no ports, and he is building ships adapted for this. Consequently, the embarkation of a landing force will most probably take place on a very wide front on an undeveloped coast. The simplest calculations show that an enormous expenditure of ballistic missiles will be required to achieve even some effect in strikes against a landing force while it is boarding its ships.

It is most probable that a large enemy landing force will proceed in the form of many small detachments from various directions in dispersed combat formations and orders. Therefore, one can hardly consider that a landing force at sea will present a suitable target for missiles with nuclear warheads of several megatons.

---

1. "The Theory of Military Art Needs Review", by Colonel-General A. Gastilovich, Special Collection of Articles of the Journal "Military Thought", First Issue, 1960, page 12

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

To deliberately rely in all cases on destroying enemy landing forces on our coast after their disembarkation or while they are disembarking, would mean to make it possible for the enemy to accomplish the preliminary mission of his operation unhindered and to put our defense in a very unfavorable situation. Landings have always been made, and apparently will be made, when there is great superiority in forces over the defenders. It must be surmised that in the first place the enemy will aim at ensuring his superiority in nuclear weapons in the landing area. Moreover, a landing will be preceded by a preliminary and direct neutralization in the full depth of our defensive forces. It is, therefore, in our view, manifestly disadvantageous to deliberately postpone combat with the landing forces until this period.

Moreover, another fundamentally important circumstance is involved. Would it be right to transfer the zone of nuclear combat to our territory? We believe not. The course of turning one's own territory into a desolate wilderness can obviously be followed only in certain directions, and then only in the most exceptional cases.

Consequently, it is clearly inexpedient and dangerous to accept the scheme outlined above for our operations in combat with enemy landing forces.

An entirely different situation is created when the Navy operates against the landing force at sea.

Calculations and experience during combat training of recent years show that even one atomic submarine armed with torpedoes can destroy more than 20 ships with troops and supplies (approximately one division of the landing force). One atomic submarine is also capable of destroying one or two large surface vessels of the screening forces, including strike carriers, which carry 60 to 100 nuclear warheads. Is this "expensive" compared with the price we shall pay if the enemy uses the indicated nuclear power against objectives

[redacted] 1.3(a)(4)

on our territory, and after that makes a landing? Other calculations could also be put forward to show that destruction of the enemy forces at sea will always be cheaper and more simple than combat with him when he is already on our territory.

Thus, until missiles attain the capability of destroying mobile sea targets at long ranges, there are no reasons for abandoning action against a landing force at sea, and even less for transferring nuclear combat with it to our territory.

Figures were given above regarding dry cargo-carrying and tanker tonnage which could be loaded by the beginning of a war. If stocks of strategic raw materials are laid down in advance, this transport fleet can be used in the first instance for shipping having military significance. It is known that up to three-quarters of the probable enemy's resources in materiel and personnel are across the ocean. Calculations show that 80 to 100 transports must arrive daily in European ports alone. If one estimates ten days for crossing the North Atlantic and returning in ballast, it can be surmised that on this communication line, 1,500 to 2,000 ships, excluding escort vessels, will be at sea at the same time.

By stopping, holding up, or reducing to the minimum this flow of troops and supplies to the main theater of war, even for a short time, especially during decisive periods of combat, we would put the enemy into a difficult situation and create the most favorable conditions for our own armed forces. This determines the strategic significance of the mission of destroying the enemy's sea communication lines. For the accomplishment of this task the Navy has far greater operational-combat capabilities in comparison with other types of armed forces.

Study of the experience of the operational training of NATO navies, as well as elementary calculations, show that the problem of giving security to such strained

communication lines cannot be fully solved by the probable enemy, owing both to the shortage of existing forces and means as well as to the impossibility of replenishing and restoring them under conditions of the disorganization of the shipbuilding industry.

It is known that besides the system of ordinary convoys, the probable enemy is looking for new ways of accomplishing the mission of protecting communication lines. Thus, he has studied the question of "monster-convoys", which permit a lesser ratio between the screening forces and the escorted transports. It is possible to accomplish the mission of securing the most crowded communication lines by the method of "patrolled zones", with ships moving in them without escorts, which provides not only economy of escort forces but, what is especially important, a quicker turnaround on the part of the transports. This method springs directly from the zonal system of defense in sea theaters adopted by NATO. Single use (without escort) may also be made of fast liners on communication lines, mainly for the transportation of troops (some of them can carry up to 6 to 8 thousand persons), wounded, radio-electronic, medical, and other equipment and other materiel in short supply.

The striving for more reliable security of sea transport can be seen from the proposed new line of development in the building of transports by the main capitalist countries. It finds its expression in the building of container (konteynernoye) and trailer (traylernoye) ships which can be unloaded and loaded quickly, in the building of ships with their own means of loading and unloading /two or three words missing/ capability of loading and unloading without tying up, and with a considerable increase of the speeds of all transport vessels. The use of submarine transport vessels, especially tankers with atomic propulsion, is contemplated in the future. As in the past, great attention is given to the development of transport-landing and debarking means.

[redacted] 1.3(s)(4)

The probable enemy's great dependence on sea and ocean communication lines and the impossibility of securing them reliably during a war give rise not only to the necessity of taking action against his sea and ocean communication lines, but also create favorable conditions for the accomplishment of this mission by the forces of the Navy.

The disruption of sea and ocean communication lines cannot, in our view, be an urgent task immediately on the outbreak of a war, for the enemy apparently counts on ensuring accomplishment of the missions of the initial stage of a war by laying in supplies in advance at the planned bridgeheads. Some time is also required for the organization of communication lines. The forming of convoys and their movement from ports in the United States to Western-European ports will take two to three weeks. There is information that the Anglo-American command is going into the question of sending "monster-convoys" from ports on the eastern coast of the United States to Western-European ports one month after the beginning of a war. It is most probable that the enemy will be faced with the problem of securing communication lines in their entirety during the concluding period of the combat for attaining the objectives of the initial stage of the war, in particular for restoring the situation in important areas, for establishing new bridgeheads, and supplying the appropriate groupings of armed forces there.

In order to fulfil the task of disrupting the enemy's sea and ocean communication lines, it will be necessary to redeploy our submarines, which raises the most important problem of resupplying submarines in the ocean, as one cannot count on doing this at shore bases which have been subjected to destruction, not to mention the fact that there will be no time for this.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In previous wars, operations on communication lines continued throughout the whole war. The ports where loading and unloading took place were not subjected to significant destruction; the shipbuilding industry succeeded not only in restoring the losses of tonnage, but in increasing it, while the use of conventional weapons against ships at sea did not give decisive results either in economic or military respects.

Present-day conditions have created opportunities for achieving decisive results in combat on communication lines. Any ports where loading and unloading take place, and communication line centers on land, can now be subjected to destruction by missile/nuclear weapons which will often produce far greater results than those attained by the protracted combat on communication lines in previous wars. For instance, the putting-out of action of the Panama Canal would lengthen the sea route from eastern United States ports to western ports from five thousand to thirteen thousand miles, or, in other words, would at once reduce transport possibilities on this communication line threefold. The putting-out of operation of the Suez Canal during the attempted armed intervention in Egypt by the British and French, even for a comparatively short period of time, when oil from the Near East had to be transported partly around Africa, forced the West European countries to ration fuel.

Under conditions of missile/nuclear war, the shipbuilding industry will be the focus of intensive activities. Being based on extensive cooperation among many branches of industry, it is particularly vulnerable to disorganization. Consequently, there can be no question of restoring tonnage on a large scale during a war. At the same time, the operational-combat capabilities of the forces of the Navy, and especially of submarines, in disrupting sea and ocean communication lines, have, as we have already pointed out, increased considerably. All this points to the fact that effective results in the accomplishment of this mission can now be attained more quickly than before.

[redacted] 1.3(a)(4)

Operations for the disruption of sea and ocean communication lines should, under modern conditions, be built, not on the principle of protracted, so-called "systematic operations" with a constant exertion of forces, as was the case heretofore, but on the principle of maximum concentration of forces on decisive axes in a limited time. An interruption in communication lines, even for a month, where the enemy has large-scale personnel and materiel losses in the main theaters of the war, will create favorable conditions for the successful execution of combat by our armed forces on the major axes.

The effective accomplishment by the Navy of the basic tasks examined above demands the carrying out of appropriate measures both in the makeup of the Navy and in the organization of its comprehensive support. What are these measures?

1. In the first place, the forces which will take part in accomplishing the main tasks in a war should be developed in every possible way:

- atomic submarines, armed with missile/nuclear weapons and long-range torpedoes;

- naval strike missile aircraft, not wheeled aircraft which are entirely dependent on airfields, but seaplanes;

- long-range antisubmarine strike forces - submarines, seaplanes, helicopters, and antisubmarine surface vessels.

Increasing autonomy, units of fire of weapons, and radius of operation, must be the main requirement in the development of these forces.

2. Insofar as the operations of our forces, especially of submarines far away from their bases, involve their return to base after using up their units of fire, which leads to a great reduction in their coefficient of combat utilization, the main problem for ensuring that the forces can operate effectively is in supplying them with

[redacted] 1.3(a)(4)

missile/nuclear weapons and torpedoes and in resupplying them at sea with material-technical resources.

It would be most expedient to follow the course of creating transport seaplanes capable of operating from bases located on internal waterways in the depth of the country and of delivering the necessary types of ammunition and supplies quickly to any areas of the ocean. The accomplishment of this mission will be made much easier if efforts are made at the same time to reduce the dimensions and weight of missile/nuclear weapons, which would considerably simplify resupply work at sea.

The first reloading of submarines at sea in the initial period of a war could be carried out to some extent by using modified transports and merchant ships sent in advance to designated areas of the ocean which are poorly watched.

We should also follow the course of creating secret depots, especially under water, in specially selected areas situated close to the areas of combat operations of our submarines.

The question of creating new, or reconstructing existing, diesel-battery submarines for service as supply bases also merits attention.

The creation of special floating supply bases, especially for missile/nuclear weapons and torpedoes, which have maneuverability and are less vulnerable than depots located on land, is absolutely essential for supplying our forces away from permanent naval bases which could be subjected to destruction at the very beginning of a war.

3. In view of the vulnerability of the main economic installations and naval bases to missile/nuclear strikes from the very beginning of a war, one cannot count on being able to carry out regular and lengthy repairs to the forces of the Navy. Only the unit method (agregatnyy metod) of repair (replacement of entire mechanisms, assemblies, subassemblies-mekhanizm, uzel, blok) can solve this problem. Repairs by the unit method can be carried out by the crew itself in any conditions, including at

[redacted] 1.3(a)(4)

sea, provided that the appropriate units are delivered there.

It is the task of industry, and not of shipbuilding yards and naval workshops, to support the unit method of carrying out repairs, i.e., to create a working stock (oborotnyy fond) of mechanisms and assemblies in advance.

We have lagged behind in methods of repairing vessels, and if these archaic methods are also followed in wartime then it is doubtful if any of our vessels will be able to put to sea again once their technical norms of maintenance of mechanisms and weapons have run out or they have been damaged in combat.

It is mainly the working stock of units that calls for repairs, and not the vessels themselves. It is necessary to provide the vessels only with the necessary assemblies for replacement. In a future war, a vessel under repair at a base is a casualty vessel.

4. In view of the possibility of destroying basic economic installations at the beginning of a war, one cannot count on being able to produce means of combat on large scales during the course of the war. This applies particularly to the Navy, as the production of its forces and weapons during hostilities is most complicated. In comparison with other types of armed forces, in the construction of submarines and surface vessels we observe the most extensive collaboration between the many branches of industry, and parallel with this, small-series production. The production of each vessel takes very much longer than the production of an airplane, missile, tank, or other types of weapons.

Consequently, for the Navy, the problem of creating and maintaining at a high state of readiness both the forces themselves and all types of supplies arises in an especially acute form. Under present-day conditions it would be rash and dangerous to rely on "ambling along" ("raskachka"), on accumulating reserves in the course of the war and making use of them during pauses of some sort.

The preparation of forces and accumulation of supplies

[redacted] 1.3(a)(4)

in advance will permit a successful solution to the problem, both in the case of a long, as well as of a comparatively short, war. The necessity of accomplishing the main tasks in a war in the shortest possible time must be one of the most important starting points in the reexamination of the operational art of the Navy (and, incidentally, as is obvious, of all the other types of armed forces).

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Theory of Military Art Needs Review", written by Colonel-General A. Gastilovich.

This article appeared in the 1960 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The First Issue of 1960 was the initial issue of this special collection, and this article by Colonel-General Gastilovich has been a subject of controversy in numerous subsequent articles.

The Theory of Military Art Needs Review

Colonel-General A. Castilovich

We all admit that nuclear weapons and missiles change the conditions of war, but having said "a", we are afraid to say "b". Dropping curtsies in the direction of missiles and introducing some minor corrections in the theory of military art, we still hold in practice to the old positions existing at the end of World War II. Past experience, traditions, and habits, taught to us for decades, tenaciously hold us back and prevent the same kind of revolution in military art which nuclear weapons and missiles created in the sphere of armament.

We strive unsuccessfully to squeeze missile/nuclear weapons into the framework of the old habitual postulates of our military doctrines only slightly "modernizing" the latter, and we forget that this doctrine was founded on the basis of using weapons of military combat fundamentally different from contemporary ones and not comparable with them.

Speaking of past world wars in a report to the Session of the Supreme Soviet in January 1960, N.S. Khrushchev noted that they formerly began on the borders of the warring countries, where the troops were concentrated. Concerning contemporary conditions he said:

"Nowadays, if war starts, military actions will develop differently, since countries will have at their disposal the means of delivering weapons over thousands of kilometers. War will start first of all in the depths of the warring countries, and every single capital, every single large industrial or administrative center, every single strategic area, will be subject to attack not just during the first days, but during the first minutes of the war. In this manner, war will both begin differently, if it is begun, and develop differently."

In another part of his report N.S. Khrushchev said: "I once more emphasize, that we already have so many nuclear weapons -- atomic and thermonuclear, and appropriate missiles for delivery of these weapons to the territory of a possible aggressor, that if some madman should order an attack against our country, [3 or 4 words missing] then we would be able to wipe such a country, or countries, completely from the face of the earth."

Defining this thought concretely, Marshal of the Soviet Union R. Ya Malinovskiy, in his speech at the same Session, said: "About

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

100 such nuclear charges, detonated within a short period of time on an industrially developed country whose territory is approximately 300-500 thousand square kilometers, will be sufficient to convert all of its industrial areas and administrative-political centers into a heap of rubble, and the territory -- into a lifeless desert contaminated with deadly radioactive substances."

It must be clear to everyone that such statements are not made for the sake of rhetoric, but are fully substantiated from the standpoint of the achievement of military technology and of the economic capability of our country.

Under contemporary conditions, the formations of missile troops of the VGK (Supreme High Command), with their unlimited range of action and colossal force of fire strike, have become the primary and decisive form of armed forces. They, rather than any other means of armed conflict "pave the way," if one may use the expression, for all other forms of armed forces, radically changing the strategic situation as a whole and the operational situation in the theaters of military operations.

The efforts of all other forms of the armed forces, which are equipped with nuclear/missile weapons, must be directed toward maximum rapid and effective exploitation of the strikes of missile formations of the VGK. In this connection, the basis for planning operations of each of the types of forces again becomes a question of the use of their own nuclear/missile weapons, and not of the number of divisions, vessels, aircraft, etc.

From these considerations it is already completely apparent that a whole series of established views of our military doctrine must be seriously reexamined, beginning with questions of strategy and operational art and ending with tactics and troop organization.

Some Questions of Strategy

Let us examine some questions concerning the initial period of war. Let us imagine NATO without two-three countries which have been taken out of the war by means of a powerful nuclear/missile strike of formations of the VGK or which have even ceased to exist in the first days of the war. This is, after all, a completely realistic perspective; let us remember incidentally, that the area of each such country is significantly less than 300 thousand square kilometers and several tens of large nuclear missiles are sufficient for its destruction. Naturally, such operations by

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

VGK missile troops completely change the nature of operations of ground troops, the navy, and aviation.

It would be naive to think that the enemy will be incapable of delivering similar powerful nuclear strikes against the territory of countries of the Socialist Camp and first and foremost against the territory of the Soviet Union. But such strikes will not be able to knock these countries out of the war.

The superiority of the socialist structure with its economic potentialities and political unity of peoples will enable countries of the Socialist Camp to withstand the first nuclear strikes of the enemy. This is further favored by the enormous territory, the inexhaustible human resources, and a relatively great dispersion of industrial and administrative centers. The imperialist bloc does not have such possibilities. For this reason, in preparing the country for the possible launching of war by aggressors, we must first of all utilize the advantages of our socialist system so as not to give the enemy the possibility of recovering after our retaliatory nuclear strike.

Of course we must take into account the consequences of the first powerful enemy nuclear strikes. As it appears to us, they will make themselves felt first of all, by the fact that in the first operation of the initial period of the war, a substantial reinforcement of troops in theaters of military operations cannot be expected by bringing up forces and equipment from the depth of the country.

Under these conditions, it appears absolutely necessary to us to review seriously certain tenets of our military strategy concerning the length of a contemporary war and the number of armed forces participating in it.

The example of the capitalist countries annihilated in the first days of the war will hardly evoke enthusiasm in the remaining countries for its prolongation. We must take into account the enormous moral shock to peoples, not to speak of the huge material losses and the human victims. It is sufficient to compare figures of human losses in previous wars with expected losses during the course of the first days or even the first hours of a contemporary war for the picture to become clear.

The losses of 33 warring countries during the four years of World War I totaled 10 million persons killed and 34 million persons

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

maimed, i.e., an average of 11 million persons per year. The losses of 72 warring countries during the six years of World War II totaled about 34 million persons killed and 28 million persons maimed, or an average also of about 11 million persons per year. According to the data of a special study by the Office of Civil Defense of the USA conducted in 1955, the losses in the course of several hours from the first aerial attack carried out chiefly by atomic and thermonuclear weapons totaled 15 million persons dead and about 24 million persons sick and wounded, altogether up to 40 million in the USA alone. In addition, about 50 to 60 percent of the country's industry was destroyed. It is well to note that in the above-mentioned study only 53 cities were subjected to the pre-arranged attack and that thermonuclear bombs were dropped on only 11 of these cities. The moral fatigue of peoples, which became evident toward the end of World War I as well as of World War II, is well known. It is easy to imagine how great this fatigue and depression will be after the first nuclear strikes in a future war.

It appears to us that after the first nuclear/missile strikes, the basis for all operations on a strategic scale must be a decisive offensive against the as yet unrecovered enemy; the more quickly and energetically that this is accomplished, the more probable that the enemy will be unable to cope with the disruption brought about by the first attack, and to organize stubborn resistance.

Whoever withstands the first enemy attack must conclude the war rapidly.

At present we already consider it possible for the tempo of operations to be 100 km in a 24-hr. period and the duration of a frontal operation to be 10 to 12 24-hr. periods. If this is so, for how many days are we preparing to wage war to achieve decisive strategic results?

At present there is already a deep-seated contradiction between demands to conduct operations on a large scale, at high tempos, without pauses, and the still extant and accepted position regarding the duration of the initial period of the war, which must continue to the end of full mobilization of forces and the beginning of the receipt of material resources and arms from mobilized industry. This is hardly realistic and apparently one must calculate on a short initial period of the war, which will be the decisive period of the entire war.

There is no need to fear the term "blitzkrieg" just because

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

this concept was compromised by the experience of past world wars. Under the conditions of nuclear war only "blitz" operations can promise victory. If victory is not achieved in a short time, then peoples will hardly be able to continue it in a slow, drawn-out fashion, especially the peoples of capitalist countries, who have a lower moral - political potential than countries of the Socialist Camp. He who has withstood the first strikes must and can conclude the war rapidly if he prepares his armed forces properly in peacetime.

Strategic art cannot be replaced by urgent demands on the moral fiber of peoples, and neither can one plan strategy on the basis of fear of calculated risk and the sacrifices connected with it.

The enemies of blitzkrieg habitually argue that our World War II losses of 1/3 of all military industry, half of the steel and coal production, 40 percent of petroleum production and output of electric power, more than half of all the rail lines and several tens of millions of the population in territory occupied by the enemy, not counting combat losses, not only did not bring about cessation of prolonged resistance but even permitted the crushing of the German fascist blitzkrieg plan and subsequently the achievement of a brilliant victory.

They forget the fact that the above-noted losses were spread out over a period of almost two years. They were inflicted only along the line of the front and within its limits; in the zone of interior they were almost non-existent. Human losses at the front and in the rear were not afforded the necessary medical and other aid available to millions of the wounded and sick of the local populace. The inhabitants situated behind the line of the front were physically almost unaware of these losses, since life in the rear continued to flow more or less normally. The picture will be entirely different now.

Under present conditions, the possibility of victory must be assured by readiness, the capacity and capability of concluding the war in the shortest possible time. The theory of a prolonged war is more acceptable at present to the monopolistic circles of the West, since the preparation for such a war costs more and consequently promises the manufacturers of arms greater profits. And in the name of profits they may not even consider the expediency of the theory.

The postulates of our military strategy concerning the size of the armed forces are also still based on the experience of past world wars and arise from the necessity of conducting war with mass,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

multi-million-man armies.

Advocates of multi-million-man armies allude to the experience of all twentieth-century wars, which showed that the growth of the destructive force of weapons in armed combat with an enemy of equal strength never brought about a decrease in the armed forces during war, but rather caused their increase. They forget that this experience is based on entirely different means of armed combat and methods of its conduct. For this reason, analogies cannot be made in this matter.

Under current conditions can operations unfold in the old manner? Can they, having begun with a relatively small number of regular combat-ready troops then continually broaden by dint of the arrival of fully mobilized large units, and finally change into engagements of numerous fronts and of multi-million-man armies? Under current conditions this is firstly impossible, and secondly, unnecessary. It is impossible because nothing will arrive from the depth of the country in time, and possibly will never arrive. It is unnecessary because after the first nuclear strikes the remaining forces of the enemy in the border zones also cannot be numerous; it is necessary to crush quickly the remains of these forces and to occupy the enemy country and, for this, operations of a completely different nature will be required from those which we are now studying.

At the present time, of the 61 divisions within the composition of the Allied ground troops of the European military bloc, there are 5 American divisions, 4 British divisions, and 8 West German divisions; the remaining divisions: 14 French, 10 Turkish divisions, and other countries - 20 divisions.

The first obliterating strike by missile formations of the VGK can be directed against the enemy in such a manner that only a border strip with a depth of several tens of kilometers (in the interest of the safety of our troops) will remain undestroyed. The taking of this strip will then become the primary mission of the advancing divisions of the first echelon; it must be accomplished also by their wide use of nuclear missiles of tactical and operational designation.

After taking the border zone, the mission confronting the troops will be chiefly the speedy taking over of zones of a greater or lesser degree of destruction and radiation resulting from the massive strike of strategic missiles. Under these conditions, the mobilizational build-up of the enemy or the approach of his large

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

operational, or even strategic, reserves can hardly be expected. It is more likely that it will be necessary to overcome the resistance of enemy troops retreating from the border zone.

To exploit the first powerful missile strike it will be completely unnecessary to deploy a large number of divisions, as was done in past wars.

Taking over the border zone and the zones of total destruction and radiation will necessitate special organization and preparation of troops, but will not, at all, necessitate multi-million-man armies. The execution of this type of mission in the European theater of military operations on a front of 600-700 km, for example, is possible with 20-25 divisions, primarily tank, rushing ahead along separate axes and in separate heated battles, pounding the large units and units of the enemy which offer resistance in the above-mentioned zones. Of course, a significant portion of these troops will suffer from enemy nuclear strikes; relatively frequent replacement of entire large units which have sustained heavy losses will be necessary. For this reason there should be 10-15 more reserve divisions behind them; in all 30-40 divisions, well equipped with tactical nuclear weapons, and which will make up the first operational echelon, will be required.

Organizationally, the strike of the first operational echelon in a zone of 600-700 km may be represented by two fronts of 15-20 divisions each, plus a certain number of divisions of airborne forces, (2 or 3 for a front). A front may consist of 2 or 3 armies of 4 or 5 divisions, each acting in a zone of 100 to 200 km, plus a certain number of divisions of the front reserve.

Forces, mobilized in the interior of the country, can arrive gradually in the theater of military operations, probably after the completion of the first operations at the front, and their principal role will consist of occupation of captured territory.

If, after taking over the territory of a country subjected to the first massive nuclear attack, the enemy does not capitulate a similar all-shattering strike may be repeated on the next country.

From the aforementioned, it does not follow of course, that those divisions which will be in action in the first operational echelon of ground troops will be sufficient for the war as a whole. It is apparent that in accordance with the forward movement a significant number of troops which have been designated for carrying out

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

occupational functions in the occupied territory will be required. A significant number of forces will also be needed in the zone of interior chiefly for various formations such as local antiaircraft defense (IPVO). Therefore, for the conduct of the war a sufficiently large number of ground troops is needed, but their over-all size, designation and nature of use will of course be different than in past wars.

The number of ground troops engaged directly in combat operations may be, as it appears to us, many times smaller than it was in previous wars.

We have outlined a concept for initial operations under European Theater conditions which is convenient for the activities of all arms of troops. To the same degree, with certain corrections for geographical conditions, it can also be applied in other theaters. In this concept, the principal leading role belongs to the operations of the VGK missile formations, but not with the aims which we now have under general review. This is not combat against enemy nuclear weapons, not the weakening of his economic potential, not combat against his reserves, etc., but the full annihilation of the enemy with nuclear warheads of megaton yield over a vast territory with the aim of knocking entire countries out of the war.

Briefly, if there is a possibility for holding out, then there is also a possibility of victory in a short period of time. Moreover, for direct combat operations at the front such numerous ground armed forces as in previous wars will be needed neither in the beginning of the war nor during its course.

Certain Questions of Operational Art

It is necessary to examine the current operations of ground troops in close connection with the operations of VGK missile formations. It appears to us that among the ranks of the latter, in addition to formations carrying out the missions of knocking entire countries out of the war, there must be formations designated for activities in the interest of several fronts conducting operations on one strategic axis. Such formations, remaining under the jurisdiction and command of General Headquarters (Stavka), could establish favorable conditions for the development of ground troop operations by means of annihilation of enemy nuclear weapons, his reserves, airfields, transportation centers, depots, and other installations located beyond the range of action of front missile weapons; by their strikes they could also reinforce the fire capability of the fronts in those

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

instances when the latter, for one reason or another, found themselves without sufficient nuclear/missile weapons. Strikes in the interests of separate fronts could be carried out either on command of the Stavka (or the command of theater forces) or upon requests of the fronts within the range of prescribed limitations.

At the same time, this VGK missile formation can carry out separate tasks assigned by the Stavka which are not directly connected with the activities of the fronts.

In all instances the VGK operational missile formation must have at its disposal its own long-range means of reconnaissance (aviation, radiotechnical, and others), in order to be able to respond rapidly to a change in the situation and to avoid multi-channel coordinations of reconnaissance tasks.

It appears expedient to us to plan the VGK missile operations as special operations for the destruction of enemy nuclear weapons, for undermining his economic potential, for combat against supply, etc. All this must be a constituent part of two types of missile operations: those operations carried out by the VGK missile troop formations with the aim of complete annihilation of an enemy country and knocking it out of the war, or operations in support of ground troops. Missile operations of the first type usually must precede operations of the second type and, subsequently, are also carried out simultaneously. It is obvious that the nature of the targets under attack will be different in each type of operation.

It is absolutely unnecessary to deploy VGK missile formations, in coordinated action with ground troops, directly in the theater of military activities or close to it. On the contrary, their placement in the zone of interior is even preferable, since this makes the work of enemy intelligence more difficult and negates the need to form a separate antiaircraft defense of these formations; their PVO can be combined with the antiaircraft defense of certain areas of the country.

The execution of VGK missile operations, the possibility of similar strikes by the enemy, the repletion of ground troops with their own organic nuclear/missile means, and the possibility of using high-yield nuclear warheads, not only in the zone of interior, but in engagements and even on the field of battle, demands thorough review of certain postulates of our military doctrine in connection with the operations of ground troops.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Above all, it is time to repudiate the very concept and expression "strike group" (udarnaya gruppirovka) as antiquated and harmful. Any grouping formed with the personnel and material of ground troops threatens to become a good target for an enemy nuclear strike and to bear extra, unwarranted losses.

In place of the creation of "strike groups" in all types of operations, it is necessary to instill the concept of "concentration of the efforts of nuclear/missile weapons". The activities, after all, of ground troops both in the offensive and in defense must take place over broad zones, approximately the same for large units in offense as in defense. This, incidentally, was recently taken into account by our probable enemies.

The bases of contemporary operations are rapid maneuver and swift attacks by small groupings (of division size), from different directions, not shoulder to shoulder, and making use of their own nuclear strikes. Even these little groupings are dispersed after a successful attack. A strike group in contemporary meaning spells death, since it forms a compact and good target for a high-yield nuclear weapon.

Contemporary offensive and defensive operations must differ from one another by the quantity of nuclear warheads alloted to their implementation and not by the number of divisions. Both in offensive and defensive ground troop operations the primary activities are nuclear strikes, swift maneuver, and short assaults with tanks and personnel. The difference rests in the fact that in offensive operations there must be a strong first echelon which permits swift destruction of the opposing enemy; in a defensive operation it is expedient to have a weaker first echelon and to designate it for holding certain transportation centers, important areas or position sectors behind large natural barriers, with the aim of slowing the tempo of the enemy offensive; defense as a whole should be based on maneuver and strikes with forces located in the zone of interior, even with the loss of territory, in order to win time and concentrate essential nuclear/missile weapons.

It appears to us that under current conditions, it is unnecessary to have second echelons, in the previous meaning of this term, either in defense or in offense. They were always thought of as a potential strike group which could be brought into battle in a new direction. At present it is much more expedient to consider everything located behind the first echelon, which is engaged in battle, as reserve, dispersed over the entire field of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

hostilities and designated as reinforcement for the first echelon during an offensive, but on the defensive - for counterattacks and counterstrikes. To overcome enemy opposition during an offensive, there should not be concentration of troops by bringing in the second echelon, but concentration of nuclear weapons and their means of delivery (nositel). Only when there is an insufficient quantity of these means can a strike be undertaken by several divisions, and then not with a compact striking group, but rather from several directions.

The possibility of enemy use of high-yield nuclear warheads in the field of hostilities obliges even those small groupings, of division size as we mentioned, to operate at a distance of 20 to 40 or more kilometers from each other or, as we frequently point out, to operate in separate directions.

Moreover, the inclination of each advancing large unit to lend assistance to its neighbor, to wheel rapidly if necessary in a new direction for a strike against the enemy rear is a binding principle of coordinated action.

Therefore, the conduct of offensive operations now requires a significantly lesser operational density but a larger number of tank divisions in the first echelon. Divisions located in the zone of interior and moving up -- are not the second echelon but rather, reserves designated as replacements for decimated divisions of the first echelon and for the circumvention of all types of obstacles.

It is necessary to reject decisively the inclination developed in previous wars toward encirclement of separate groupings and the formation of rings around them. This tendency is very viable and has remained with us as an inheritance from the period when there were no other methods for annihilation of the enemy left in the rear of advancing troops. Nowadays, the enemy left in the rear must be destroyed either in meeting engagements by reserve large units and units or if stationary, they must be annihilated with nuclear strikes. The latter, of course, is preferable.

In the training of troops, it is necessary also to reject decisively the cultivation of the principle of break through the enemy's prepared defenses. It is possible, of course, in individual instances when the enemy defense cannot be bypassed or annihilated by nuclear strike. In the main, however, under conditions not involving solid fronts or heated battles, the breakthrough of an enemy prepared defense has ceased to be the primary form of offensive

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

actions, but is yielding to meeting engagements and envelopment.

The taking of radioactively contaminated zones created by the enemy acquires great importance. It must be carried out by large units, depending upon the tasks they are fulfilling, the meteorological situation, and the degree of permissible dosage of radiation received during the period of action. Depending upon these conditions, the contaminated zones are taken either by a rapid forward push or by bypassing, or in the final analysis, the troops continue to carry out their mission in the contaminated zone without regard to possible losses. All discussions regarding the creation of passages into contaminated zones, the surmounting of them in helicopters and others are utopian at the present time.

In planning contemporary offensive operations on the scale of a front and armies, it is impossible to proceed from an single "D" (day). In terms of time, operations will flow in different directions, at different tempos and it is more advisable to plan them by calendar days (except, of course, the initial retaliatory missile strike). Moreover, concrete army and large unit tasks can be established for only 1-2 days and for a longer period it is sufficient to indicate the general direction, the nature of the activities and final goal of the operation. More detailed planning is highly problematical, since sharp changes in the situation are unavoidable as a result of enemy nuclear strikes.

The tempos of contemporary operations may be planned, as already mentioned, up to 80 to 100 and more kilometers during a 24-hr. period but it must be kept in mind that, as a result of enemy nuclear strikes on our deep rear, the front will not be able to rely on systematic delivery from the rear of the country. Everything which is essential must already be stored in the theaters in peacetime and such supplies as POL must, to a significant degree, be sought out from war trophies in the course of the advance.

It is also essential to take into account the cumulative physical tension on tank and truck drivers (it will be necessary to have two reliefs for interchange of crew members) and the large number of vehicles which will go out of commission.

Vigorous maneuver and nuclear strikes must become the basis of contemporary defense. He who sits in place, even in prepared positions, will be knocked out by nuclear weapons or bypassed. Only a relatively small part of the forces can hold separate areas or positions with the aim of slowing the tempo of the enemy advance along axes which

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

are convenient for him and, consequently, cluster his battle array and operational formation. In this connection an important role in defense is played by broad utilization of obstacles and terrains presenting natural obstructions for slowing the tempo of the enemy advance. However, the fate of modern defense is decided in the final analysis by the maneuver of missiles, chiefly the shifting of their trajectories, and the availability of nuclear warheads, in conjunction with counterattacks and counterblows of the reserves.

It appears to us that under contemporary conditions defense, in the past meaning of this term, can take place only on a tactical scale. Army and front operational defense, deliberately subordinated to the interests of offensive operations in other directions or dictated by a sharp change in the situation in the enemy's favor, will, of course, also have its place. But it must be based on the same methods of operation as in offensive operations, i.e., on heated meeting battles and engagements. For this, the army and front may have a number of large units and a scale of zones of action equal to those of an army and front carrying out offensive operations. The difference will be in the presence of a smaller quantity of nuclear warheads, which will necessitate loss of a part of the forces and territory in order to win time.

Defensive operations of the front and army, differing from offensive operations in aims of action and quantity of nuclear weapons, will resemble the latter in methods of large unit tactical operations.

In defensive operations, certain armies of the front and certain large units of armies, taking advantage of a convenient local situation which has arisen as a result of swift actions or nuclear strikes, will frequently carry out an offensive with limited goals.

In a contemporary operational defense, the formation of defensive zones is not advisable because they do not justify their designation. Any large unit defending itself in place will be annihilated by nuclear strikes of the enemy or simply bypassed. On the operational scale, the term "stable defense" should be relegated to the archives because under modern conditions it can be neither solid nor stable. Slowing the tempo of the advancing enemy by means of defense is based on counterattacks and counterstrikes carried out from different directions, on skilful and swift disengagements from the enemy, and on broad use of barricades and utilization of natural terrain obstacles, until the time a possibility presents itself to destroy the enemy with a nuclear strike.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In connection with this it is necessary, evidently, to re-examine our views on the nature of so-called counterpreparation (kontrpodgotovka) in defense and on organization of counterstrikes. In these questions we continue to proceed from the concept of the solid and relatively stable front.

It appears to us that a limited quantity of nuclear weapons in the defense will not permit a breakup of the enemy offensive with one or two massive nuclear strikes, especially since he will not form compact groupings for his offensive. Apparently, instead of counterpreparation, it will be necessary to restrict oneself to daily and rapid annihilation of disclosed enemy means of nuclear attack and to individual (to the extent possible) nuclear strikes at various times on the most dangerous of his tank divisions which have broken through. If, however, the availability of nuclear weapons permits the delivery of a massive strike capable of breaking up the enemy offensive completely, then this is already not counter-preparation but going over to the offensive.

It is more expedient to carry out counterstrikes in operational defense, by means of meeting engagements, not with a compact grouping especially created for this purpose and deployed on a definite line, but with several divisions operating simultaneously, though from different directions.

Anti-debarkation defense along the coast by ground troops can also have no defensive zones either on the coast or in the zone of interior. In ports and in vulnerable landing sectors along the coast there can be separate tank subunits and units designated basically for combat against airborne landings and for initial repulsion of debarkations of the enemy in landing-debarkation craft.

The basis of anti-debarkation defense must be the maneuvering activities of large units which move up from the interior of coastal zones and, in meeting engagements, pound the enemy utilizing nuclear weapons.

Of the now generally accepted means of anti-debarkation defense, only the construction of obstacles, both in the water as well as on the land, can achieve much significance.

Enemy amphibious landing operations, while enroute at sea, do not merit expensive and cumbersome operations against them by the navy and long-range aviation. The basis of their annihilation can

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

be missile strikes in embarkation and debarkation areas; while enroute at sea, it is again more expedient to annihilate landing forces by strikes with missiles having nuclear charges of several megatons. After the discovery of the landing forces at sea, these attacks can be calculated on the basis of their passage of a definite point (area).

Certain Questions of the Development and Organization of the Types of Armed Forces

The changing of certain strategic and operational points of view is unavoidably bound up in the review of the programs for development and organization of the different types of armed forces. This development must, first of all, evolve only from the needs of the initial period of the war, since a long, drawn-out nuclear/missile struggle is impossible; secondly, it must develop under the banner of the indubitable priority of nuclear/missile troops. In this respect it is expedient to develop primarily missile troops of the VGK, capable of using missiles of megaton yields.

Missile troops of all types -- VGK, operational, and tactical -- must develop in the directions of:

- increasing their firing rate (skorostrelnost); in this respect the introduction of solid missile fuels has decisive significance; missiles must be per se ready projectiles, fully assembled and requiring only the establishment of the flight program;

- perfection and automation of the process of tying in the launching mounts (carriers) to the terrain;

- perfection of missile guidance systems, not subject to jamming;

- perfection of missile carriers capable of changing the launch area quickly; in this respect an important role must be played principally by "air-surface" type missiles on seaplanes (gidrosamolet), missile-carrying submarines, and missile trains (poyezd) (for strategic missiles);

- perfection of the system of centralized command of launching missiles from widely separated command points.

It must be acknowledged directly that in their present state, missiles of tactical and operational designation are still not sufficiently suitable for the missions assigned to them because of their

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

low firing rate conditioned by complex preparations for launching, for retargeting and for changing of firing positions.

The ground troops as a whole must develop in a form transportable by air. Perfection and introduction of lighter type tanks (since any armor is penetrable) suitable for transport by air is essential. The great importance which is attached to the ability of ground troops to take ruined and contaminated zones and water barriers requires significant development of engineering troops; however the most important mission of the engineering troops must not be fortification in the existing meaning of this term, i.e., not the construction of positions and of anti-atomic shelters but the rapid preparation of missile launch sites, establishment of obstacles, road construction, and provisions for the surmounting of large water obstacles.

The air forces, it appears to us, have not yet lost their significance to the degree that they should be ignored. Discussion should concern only the change in their role in warfare and, subsequently, a change in their composition and organization.

Long-range aviation, armed with missiles of the "air-ship" class, is (in conjunction with submarines) a good means of combat with mobile carriers of nuclear weapons at sea and one that is difficult to replace. In view of this, it is apparently advisable to include it in the composition of the navy.

Front air forces (VVS) are also needed, though of a type other than those now available. Certainly, front bomber aviation is departing the scene, since its missions can, to a significant degree, be carried out by missiles. Nevertheless, on the field of modern battle and engagements there will be many important small and mobile targets whose annihilation by missiles is still improbable. An aircraft of the fighter-bomber type is needed which, on its own, could find the target and annihilate it; such an aircraft must be capable of great acceleration, permitting it to appear and depart rapidly (this may be achieved with the aid of rocket boosters): at the same time it must be capable of carrying out combat missions at relatively low speeds as well. An aircraft flying at a speed equal to Mach 1-2 (M-2M), is poorly suited to seek out small and mobile targets, even with the use of radar equipment.

Fighter aviation within the composition of the VVS of a front is essential, as a more maneuverable component of the PVO, as long as aviation remains one of the principal carriers of nuclear weapons

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

for the enemy and as long as ground antiaircraft missile systems do not possess a sufficient range of destruction.

In addition, the front needs a manifold troop (army) aviation for observation and reconnaissance, including radiation, for liaison, command, and transport. Such aviation must undoubtedly develop as non airfield-based. It may consist of helicopters and other flying machines, for example the type well known in foreign literature under the term "flying saucers" (ground effect machine-turbolet).

The VVS of the front must have a much greater number of reconnaissance aircraft than they have at present.

Finally, greater-capacity transport aviation is needed as a resource of the Supreme High Command.

The VVS of the front (air army) is not designated under modern conditions for the execution of any independent air operations, and is the means for directly coordinated action with combined-arms armies. For this reason, their composition must include several aircraft divisions of fighter-bombers because only the latter are favorable for combat against mobile carriers of nuclear weapons and the advancing reserves of the enemy. In this connection, however, it is inadvisable to distribute the VVS forces of the front for support of definite armies or divisions; it is better to utilize them centrally, under the jurisdiction of the VVS commander.

The Navy. The future at sea belongs to submarines and to missile-carrying seaplanes which are not bound to airfields and which are capable of long-range operations. These, it would appear, should now be developed.

The basic mission of the fleet -- to annihilate carriers of nuclear/missile weapons at sea which as a consequence of their mobility, have greater survival chances. Such carriers will be missile-carrying aircraft and missile-carrying atomic submarines. As a result of their high radar-image contrast and, consequently, their vulnerability aircraft carriers and other surface vessels apparently will soon depart from the scene.

Under contemporary conditions it is hardly possible to imagine large amphibious landing operations of an operational, and even less, of strategic significance. A landing force is always, at some stage of its activity, a compact group or it does not make sense; but this

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

condition spells destruction for the landing force. The possibilities are all in favor of its annihilation by nuclear/missile weapons while it is still at its bases or while it is at sea.

Surface vessels of the fleet will not be able to play a significant role in armed conflict. Their utility will probably be limited to coastal areas under heavy PVO cover for execution of support missions. As far as protection of ocean supply transport is concerned, even now they are of little use for carrying out this mission.

Antiaircraft defense of troops and the country, as it appears to us, is on the correct course of development, chiefly of antimissile resources in the form of the creation of fully automatic systems of antiaircraft missiles.

The age of tube antiaircraft artillery is irrevocably receding into the past and it is only in the antiaircraft defense of troops that small-caliber tube antiaircraft artillery may still have some significance for the protection of small subunits from low-flying aircraft.

The principal antiaircraft defense of troops and the country must be an automatic system of antiaircraft missile installations of various ranges which could cover, not installations, but separate large areas, and could resolve the task of protecting both the troops and the territorial installations of the country (in these areas). Separate antiaircraft defense of troops, except for the self-defense of small subunits mentioned above, appears to us to be an antiquated tradition. Fighter aircraft aviation within the system of antiaircraft defense will also become archaic in the near future. It is needed only until antiaircraft missiles have achieved the necessary technical perfection.

A new type of forces. In addition to existing types of armed forces the necessity has sprung up, in our opinion, for the creation of a new type of force which is not designated for direct conduct of combat operations, but which is extremely important, nonetheless, under conditions of nuclear/missile war. We have in mind troops, possibly called rescue-rehabilition (spasatelno-vosstanovitelnyy), which are designated for operations in the country's interior, in areas subjected to enemy nuclear attack. Their basis should consist of medical service and rehabilation units and large units.

In contrast to other types of forces, these troops must be

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

especially massive, organized according to territorial characteristics and trained without being pulled out of production. We have something similar now in the form of civilian formations of the antiaircraft defense (MPVO). But these formations exist mostly on paper, are not supported from a material-technical standpoint, are semi-voluntary organizations, and are not properly directed by anyone. In addition, organs of the MPVO are concerned with a very large number of problems which, in essence, are the prerogatives of governmental authority, such as communications, supplying the population with food, evacuation, etc.

It appears to us that such very important undertakings as medical assistance to the suffering populace and rehabilitative work, i.e., measures permitting the people to withstand enemy nuclear attack, must be implemented by special troops. Their cadres and necessary equipment must be maintained in peacetime and they must be assured mobilizational buildup under the leadership of organs of military control with the initiation of military activities.

Questions of Control. From the standpoint of the nature of control of operations, the new forms of armed conflict do not introduce any basic changes. As in the past there will be need for intelligence and collation of its information, an appraisal of the situation, a decision, and its transmittal to executors, supervision of execution, influence on the course of events by changing the tasks of subordinate troops, or through the influence of the senior commander's means exerted on the enemy, the informing of the commander and of adjacent units. However, the methods of control and the means by which they are implemented experience significant changes.

The method of direct personal contact in operations is of little value today. It can lead only to a waste of the senior commander's time and promote incorrect decisions based upon impressions of one center of combat operations. This method is admissible now only in combat on a subunit level, but not in operations.

The need to see the field of combat along the decisive direction also has little admissibility now. This need arose from crushing the enemy with masses of troops which were in direct contact with him. This will not usually happen, now.

The most important thing in control is quick reaction to a change in the situation, a rapid tempo of control, and, consequently, the well-known need for its mechanization, automation, and reduction of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the number of its documents.

Even now wire telegraphy and telephone communications should be added to obsolescent means of control as they will not be able to keep pace with the operating tempo of troops.

Apparently even such an attribute of control as the preparation of large unit and army command posts with all types of shelters (dugouts), by the forces and equipment of engineer troops, is becoming obsolete. The rapid tempos of battles and operations require highly mobile command points using available places of cover (cellars, buildings, tunnels, quarries, etc.).

The recording of meteorological conditions and their prediction become a very important factor in operational planning and in daily control. In this connection, the creation of special meteorological units in all staffs from division to front is absolutely essential.

Until automatic systems permitting rapid and accurate determination of coordinates for missile launchers are worked out, it is essential to have in the staffs of armies and fronts a separate topogeodetic service with subordinate special units to support missile units and large units.

* * *

In this article we have only touched upon some of the most topical questions of military art. In connection with the development of nuclear/missile weapons, the total number of postulates in need of review is undoubtedly much greater. Many of the questions touched upon by us are set forth only by way of posing them and bringing them to the attention of military-theoretical thought. Therefore, the judgements of the author cannot lay claim to exhaustive completeness or infallibility.

Intelligence - to the Level of Modern Demands

by

Major-General Ya. Malakhov

Lieutenant-General M. Kochetkov's article, "The Elimination of the Lag in Operational and Tactical Intelligence"[1] touches on a series of problems, the practical solution of which has important significance in raising intelligence to the level of modern demands.

While we entirely share the author's opinions on the basic tenets of the article, we should like to state some views on this problem.

Recently, both in the pages of the military press and at the critiques of command-staff exercises and troop exercises, there has been repeated talk about raising the role of intelligence, about its exceptional significance for the achievement of success in combat and in operations, and about the lagging of intelligence means (sredstvo razvedki) behind the means of destruction. Unfortunately, however, in practice, nothing is being done to bring the potentialities of intelligence into accordance with the demands which present themselves and with the tasks which confront it.

In our opinion, this results from the fact that there is no single intelligence organ (razvedyvatelnyy organ) in the Soviet army to direct operational and tactical intelligence in the military forces.

1. Special Collection of Articles of the Journal [redacted] 1.3(a)(4)
"Military Thought", Second Issue, 1960.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In actual fact, the Chief Intelligence Directorate (Glavnoye Razvedyvatelnoye Upravleniye - GRU) of the General Staff has no such organ, and its guidance is limited to agent and radiotechnical intelligence in border districts and in groups of forces.

The intelligence department of the Main Staff (Glavnyy Shtab) of the Ground Troops does not direct operational intelligence in the districts on a daily basis, but at operational-strategic command-staff exercises and maneuvers the reconnaissance detachment (razvedyvatelnyy otryad - RO) of the Main Staff of the Ground Troops prepares the appropriate materials for critiques and draws conclusions on its state.

This all results in the fact that the supervision of the training of personnel and of the activity of operational and tactical intelligence are carried out at the center by several chiefs, and are in essence uncoordinated by anyone. Thus, for instance, the chiefs of intelligence of border districts receive directives from several chiefs of directorates and departments of the Chief Intelligence Directorate, from the chief of intelligence of the Main Staff of the Ground Troops, from the Chief Directorate of Combat Training and sometimes also from the headquarters of troops of the Antiaircraft Defense (Protivo-Vozdushnaya Oborona - PVO) of the Country. Each is interested, not in the state of intelligence in the district as a whole, but only in individual questions which concern their department (vedomstvo). This seems to be the only way in which one can explain a situation in which the problematical questions of intelligence are not resolved. Moreover, we still have no manual of military intelligence, or technical means for reconnaissance against nuclear/missile weapons, or appropriate means of communication, while the methods of intelligence employed by the troops are extremely primitive and do not ensure the solution of this complicated problem.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The absence of a single organ for the supervision of operational and tactical intelligence in districts results in the fact that the resolution of even simple problems takes years. For example, combat reconnaissance patrol vehicles (boyevo-razvedochnaya dozornaya mashina - BRDM) began to reach the troops in 1958, but the problem of installing a machine gun and optical observation instruments in them has not been decided to this day.

It is known that no new technical means of intelligence will give good results if there are not well-trained personnel to use them.

The Commander-in-Chief of Ground Troops, Marshal of the Soviet Union V. I. Chuykov, at the critique of the command-staff exercise "DON", explained: "Equipment in itself, no matter how perfect, will not ensure the radical improvement of the state of intelligence. Commanders and staffs at all levels must learn the correct way of organizing intelligence practically and of directing it continuously".

Meanwhile, intelligence officers, who would know intelligence equipment well and who would know how to organize and carry out intelligence in modern operations, are not being trained properly in the military-educational institutions.

The higher intelligence courses for intelligence officers, the intelligence faculty of the Academy i/n M.V. Frunze, the intelligence sections of the Academy of Armored Troops and of the Air Forces Academy, as well as the Military Institute of Foreign Languages, have been disbanded. It seems that in the existing higher military-educational institutions very little attention is devoted to the training of officers in the intelligence field. There are, therefore, frequent cases of officers who return to the troops after graduating at these institutions without even elementary knowledge, not to mention ability, in the organization of intelligence.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

All of this has resulted in the fact that only a limited number of intelligence officers with specialized academy education remains with the troops. The situation with regard to intelligence officer personnel can be illustrated by the example of the Belorussian Military District. Of all the intelligence officers in the district, starting with the intelligence chief of a unit and higher, only 20 percent have graduated from higher educational institutions. At the same time, in the last three years only one officer has come from an Academy for intelligence duty with the troops of the district. All of this makes it necessary to select for engagement in intelligence duties officers who have neither theoretical training nor practical ability in this work, which in turn affects the quality of the intelligence training of the troops and the combat training of intelligence subunits.

In our view, there is an urgent need for the serious reorganization of the training and advanced training of the intelligence officers of all types of armed forces and of all arms of troops.

In the training of intelligence officers, in our opinion, attention should be given, first of all, to the study of the technical means of intelligence and to their potentialities, to modes and methods of organizing and executing reconnaissance against nuclear/missile weapons, and to knowledge of the organization, armament, tactics, and operational art of the probable enemy. Taking into account the fact that there are almost no well-trained interpreters with the troops, and that the military-educational institutions are not training officers who know foreign languages, it is advisable that the training of officers who are proficient in foreign languages should be organized.

We share completely the opinion of the author of the article on the revival of intelligence in the arms of troops, but the solution of this problem in the sequence of the headquarters of a front-army-division must lie not through the channel of chiefs

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

of intelligence of the appropriate commanders of arms of troops, but in the inclusion of such specialists in the intelligence sections, departments, and directorates of the combined-arms headquarters. We consider this method more expedient, firstly, because in the conditions of modern combat time (not in hours but in seconds and minutes) acquires primary significance, and this demands the shortening to the minimum of the channels (instantsiya) along which tasks for, and information from, intelligence organs pass; secondly, because, in order to evaluate the situation properly, all information must flow to a single organ, which would collate, accumulate, and analyze it and draw the appropriate conclusions and thirdly, because, as Marshal of the Soviet Union V.I. Chuykov pointed out at the critique of the exercise "DON", "Only the combined-arms headquarters can plan intelligence activity purposefully and can utilize, for its execution, the various forces and means, taking into account their capabilities and the conditions of the situation".

It is most necessary to review and to strengthen technical equipment as a means of obtaining intelligence data, as well as the organs concerned with their processing. Let us take, for example, radiotechnical intelligence units (OSNAZ). These are of low mobility because of the bulk of the intelligence equipment which they carry and, perhaps, are simply not suitable for operations under field conditions.

As is known, the commanding officers of motorized-rifle and tank divisions, and the commanders of combined-arms and tank armies, have received and have at their disposal long-range missile means of destruction, but so far they possess absolutely no forces or means capable of carrying out intelligence to the possible depth of fire-destruction of targets.

We consider that each commanding officer (commander) must have at his disposal the forces and means necessary to assure continuous and vigorous conduct of intelligence, at least to the depth of the range of fire of the means available in the composition of a given unit, large unit, or formation.

DATE OF INFO: 1960

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "Questions of the Control of Missile Units in an Offensive Operation", written by Major-General S. Kuznetsov and Major-General A. Tikhomirov".

This article appeared in the 1960 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1960 First Issue was the initial issue of this publication.

[redacted] 1.3(a)(4)

1.3(a)(4)

Questions of the Control of Missile Units in an Offensive Operation

Major-General S. Kuznetsov

Major-General A. Tikhomirov

The organization of the control of missile units employing nuclear warheads continues to remain the subject of special attention for combined-arms commanders as well as for missile specialists (spetsialist-raketchik). A number of articles devoted to this question have already appeared in Collections of Articles of the Journal "Military Thought".

As is known, during the critique of the operational-strategic staff exercise which took place in the Ukraine in September 1959, Marshal of the Soviet Union Comrade Grechko noted the shortcomings uncovered during the exercise in the realm of control of weapons of mass destruction. In particular, it was pointed out that because the most expedient forms and methods of control of these means have not yet been found, the coordination between intelligence organs, the operational command, and the commanders of the artillery and the air army on questions concerning the use of nuclear weapons, involves an intolerable waste of time measured in terms of many (4 to 6) hours. Similar defects were noted during a number of other exercises. In connection with this, there is an imperative necessity to find those methods for the control of weapons utilizing nuclear warheads which would require the least possible time for the destruction of a target (from the moment of its detection to the nuclear strike).

At the present time the organization of the control of missile units and tube artillery employing nuclear ammunition is reflected as follows. For the fulfilment of missions in the interests of the main grouping of army troops, the missile units and units of tube artillery employing nuclear ammunition are brought together in an army special artillery group (ASAG). In an offensive operation the army may be reinforced with missile units allocated for solution of tasks of tactical (range of fire of not more than 35 km) as well as of operational significance (range of fire up to 300 km). Furthermore, it can receive an additional 1 to 2 tube artillery divisions employing nuclear ammunition. Therefore, the composition of the ASAG, as regards its tactical and technical characteristics as a deliverer of nuclear warheads, will be exceptionally varied, and this will greatly impede the achievement of control of this group during preparation

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

for and in the course of the operation. Objections to the creation of the ASAG, in connection with the above-mentioned situation, have been stated in detail in print. In addition to these, we would also point out the following.

It is recommended that the ASAG utilize as its staff the staffs of the artillery divisions of the Reserve of the Supreme High Command (RVGK)[1], which are advancing as reinforcements for the army. Furthermore, the artillery division commander who is appointed as the commander of the ASAG is not relieved of his responsibilities for the activities of his organic large units, which were transferred to reinforce the large units of the army.

The commander of the RVGK artillery division and his staff have organic means of control which permit the organization of control of only their own large units. When appointed as commander of the ASAG, the commander of an RVGK artillery division is obliged to leave to his deputy part of the means of control, exercised by the division headquarters, for ensuring the control of organic large units of the RVGK artillery division allocated to reinforce the army. As a result, the ASAG commander and the deputy commander of the RVGK division will not have sufficient means of control; this will lead to unreliability of control and, in particular, to loss of time in the transmission of various orders and commands and in the receipt of information from below. Therefore, the use of the RVGK artillery division staff in the capacity of the ASAG staff is, obviously, inexpedient. It will in no way promote the speed of delivery of nuclear strikes.

We further consider that one of the causes of delay in the delivery of a nuclear strike on detected, unscheduled targets is the unnecessary centralization of the decision of the question of the allocation of nuclear warheads. Usually this is done in the following manner. Let us assume that the headquarters of artillery of a front (army) has received a report from an aircraft about a detected target (for example, a "Corporal" launcher). The commander of artillery of the front (army), not having the means to destroy the target with firepower of conventional means, reports this to the troop commander and requests permission to use missiles with nuclear charges. The troop commander, having a very limited reserve of nuclear warheads, will first determine the possibility of the destruction of this target by

1. Marshal of Artillery S. Varentsov. "Combat Employment of Artillery in Offensive Operations of an Army and Front. Collection of Articles of the Journal "Voyennaya Mysl", 1958, No. 5 (43), page 13 .

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

conventional air weapons, and only after this will be give the appropriate instructions to the artillery or air army commander.

Having received the troop commander's decision, the artillery commander gives instructions to the commander of the missile unit (the ASAG commander) to prepare for a strike on the target with a nuclear warhead. Then he will have to be provided with the corrected target coordinates and the order for expenditure of a nuclear warhead. All these conversations and transmissions of commands waste a considerable amount of time which is quite sufficient for the "Corporal" launcher to have carried out the firing of a nuclear warhead or to have changed its location site.

The situation becomes even more complicated in the event one must decide an analogous task in the course of a successfully developing offensive operation, with high tempos of movement, the absence of a continuous front, a high dynamic of operations, and unexpected and sharp changes in the situation. Under these conditions, an imperative need arises to impart the greatest possible autonomy to large units in conducting combat operations, which, of course, must be supported accordingly. The division commanders will not have time to await the army commander's decision regarding the question of destruction by nuclear weapons of targets presenting an immediate threat to the division's units.

On the basis of the above, the conclusion can be drawn that the existing rigid centralization in deciding the question of the use of nuclear warheads against unscheduled targets becomes a factor of a negative order. In order to shorten decisively the time from the detection of the target to its destruction by nuclear warheads, partial decentralization of the use of these warheads is essential. It can be realized only if the division commanders obtain as reinforcement missile units (units of tube artillery employing nuclear ammunition) and receive the right to make decisions regarding destruction of targets with nuclear ammunition within the limits of their expenditure established by the army commander.

Which missile units can be used for reinforcement of the divisions? First of all, of course, units of tactical missiles having a firing range of up to 35 km. Such a range permits the missile support of division units with one shift of siting area during the course of a day's advance. In addition, it guarantees firepower maneuver not only within the limits of the entire width of the division's zone of advance, but also within a considerable part of the zones of advance of neighboring divisions. This situation provides the commander of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

artillery of the army, within definite boundaries, with an opportunity to use the missile units assigned to the division, for fulfilling tasks of army significance.

During preparations for an offensive operation, the combined-arms army may, count on reinforcement by one regiment of tactical missiles. This will permit each division of the first echelon of the army to be strengthened by at least one battalion (divizion) in the direction of its main strike.

As is known, under existing organization missile battalions are uniform: part of them are armed with missiles having firing range of up to 20-25 km, part with a firing range of 30-35 km. These two types of missiles have different magnitudes of probable error (otklonenive), and therefore may not be utilized for the execution of all tasks. Missiles with a range of fire of 20-25 km, having less dispersion, are more suitable for the destruction of targets located in the immediate vicinity of friendly troops. At the same time, the tactical-technical characteristics of missiles having the maximum firing range of 35 km practically exclude the possibility of their use with nuclear charges against targets which are located in the immediate vicinity of friendly troops. Therefore it is desirable to reinforce the division with missile subunits of tactical designation with various tactical-technical characteristics; this would necessitate battalions of mixed composition. With regard to the supply of warheads to such a mixed battalion, there will be no special inconveniences; one workshop can assemble nuclear charges on these and other missiles of tactical designation.

It is inexpedient to include missile subunits, assigned to divisions, in just any artillery group, first of all because of these subunits are designated for resolution of only particularly important tasks, and secondly because they usually have a very limited number of warheads. Missile subunits must remain directly subordinate to the commander of the artillery division.

The commanding officer and staff of a missile regiment (polk), after its battalions are assigned to divisions, will retain the functions of ensuring the timely preparation of the battalions for fulfilment of firing tasks during the period of artillery preparation and artillery support of the offensive, the control of the combat activities of the battalions, assistance to them in organizing meteorological, ballistic, topographical, and technical support; the delivery to battalions of warheads having nuclear, conventional, and chemical charges, and also the control of the maneuver of battalions during regroupings. In addition, they are the ones who will provide direction in supplying the battalions with all kinds of materiel

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

items and repair equipment. Therefore, the headquarters of the missile regiment will be used during the preparation for and in the course of the operation in the same manner as the headquarters of the artillery breakthrough division of the RVGK.

For the fulfilment of tasks of army significance, the combined-arms army may be reinforced by several battalions of operational missiles with a firing range of 150-300 km. These battalions will comprise that portion of long-range weapons which it is advisable to leave directly subordinate to the commander of army artillery. If the army is reinforced with two or three battalions, then they will be under the direction of the commander and staff of the missile regiment. If, however, the army is reinforced with only one battalion, then naturally it will be under the direction of the commander of the battalion and his staff.

The proposed distribution of missile units and subunits should not be regarded as a categorical rejection of the centralization of their fire control by the commander of artillery of the army. During the period of artillery preparation of the offensive, it is advisable to centralize at the army level the use of the subunits and units employing nuclear weapons, taking into account the tasks which are fulfiled by divisions. However, for this there is no necessity to withdraw these missile units (subunits) from the divisions and to create an ASAG. It will be sufficient if the army artillery commander will provide the commanders of artillery of divisions with the tasks which, according to army plan, must be fulfiled by missile units and subunits with nuclear shells and shells with conventional charges, i.e., the centralization of fire control of these units and subunits will be carried out on the same bases as the centralization of fire control of tube and rocket artillery employing shells with conventional and chemical charges. The centralization of fire control of units and subunits employing nuclear weapons may also be required during a breakthrough of the enemy's defense zones in the course of an offensive operation, and in some other instances.

A proposal concerning the creation of front special artillery groups (FSAG) was expressed in print. We consider this proposal to be groundless. At the present time the headquarters of artillery of a front does not have the possibility of choosing from among its personnel an artillery staff, with corresponding means of control, which could head the FSAG. And in this regard there is no necessity to create such a group. It is doubtful that there can be more than one or two missile regiments subordinate to a front in the very near future. These regiments will have a very limited quantity (but very

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

powerful) of nuclear weapons in connection with which the setting-up of tasks for regiments and the supervision of their fulfilment will not burden the staff of the front artillery.

In those cases where the front has 3 or 4 missile regiments (which apparently, will be a rare exception) the necessity for the creation of an FSAG will arise. But only a specially created staff having the necessary means of control will be able to head such a front group. Such a staff must arrive to reinforce the front concurrently with the arrival of the missile regiments.

A few words about reconnaissance. There is no necessity to prove the exceptional significance which reconnaissance of the enemy has for all units employing nuclear weapons. It is obvious. We wish only to note one circumstance which, to an intense degree, impedes the employment of nuclear weapons. The fact is that the missile units and units of tube artillery employing nuclear warheads, do not at the present time have the reconnaissance means which would permit them to conduct reconnaissance of targets for destruction by nuclear weapons and to maintain control over the results of nuclear strikes. The front aviation conducts reconnaissance for the missile regiments of operational designation; this can be considered normal. Reconnaissance for tactical missile regiments is conducted basically by those means which belong to the army artillery. These are principally the ground artillery reconnaissance means, helicopters, and individual artillery fire-adjusting planes from among the artillery fire-adjusting planes assigned to the army for the operation.

In an overwhelming majority of cases, the enemy's atomic cannon and rocket launchers of the "Honest John" and "Lacrosse" type may be detected only by photography from the air. A great deal of time passes before the data regarding the enemy's atomic cannon (rocket launchers), after its processing and after the decision of the army commander, arrive at the missile battalion (battery) which must destroy this gun with a nuclear warhead.

The situation is no better as regards the detection of enemy forces and combat equipment in the course of an offensive. The basic causes of this situation appear to be the extremely inadequate number of artillery fire-adjusting planes which are usually assigned to the army, and the complete disparity of the tactical-technical characteristics of existing artillery fire-adjusting planes with contemporary requirements, and finally, an exceptionally strict centralization of their use.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The strict centralization of the use of artillery fire-adjusting planes was justified to some extent by the fact that aerial reconnaissance was conducted basically in the interests of army artillery groups and army special artillery groups. However, when missile subunits are assigned to divisions, the previous procedure for use of artillery fire-adjusting planes, in accordance with the general army plan, obviously becomes obsolete. The time has come to provide the large units with the means of aerial reconnaissance which could also be used for adjustment of fire of tube artillery and for the reconnaissance of the enemy's means of nuclear attack in the tactical depth of his defense. These means of reconnaissance must be aircraft with the appropriate tactical-technical characteristics. The presence of aerial reconnaissance means within the large units will provide for a more rapid reaction to detected targets on the part of the large unit commander, and consequently, will shorten considerably the time between the moment of the detection of the target and the delivery of a nuclear strike against it.

Considerable significance for the rapid implementation of nuclear strikes with missiles on unscheduled targets, is attributed to the correct organization of meteorological support of missile units.

Missiles (raketa) of tactical designation, as is known, have solid fuel. Their readiness for launching is determined by the time necessary for calculations in setting-up the sighting mechanisms, mounts, checkout, and heating (pogrev) of the explosive mechanism. With the possession of the most recent meteorological data, all the aforementioned may require up to 15 minutes from the moment the battery receives the command to open fire to the launching of the missile. In the absence of the most recent meteorological data, twice as much time will be required, since it will be necessary to gather information regarding atmospheric conditions and to prepare a meteorological bulletin.

With the possession of a valid meteorological bulletin and favorable conditions, not more than 30 to 40 minutes is required in order to launch a missile of operational designation which is on a launch pad (puskovoy stol). If the meteorological bulletin is not current, however, an additional 1 to 1½ hours may be required for the launching of the pilot balloon (shara-pilot), the processing of the data obtained, and the compilation of the meteorological bulletin. Furthermore, approximately an additional 15 minutes will be required for the preparation of data for setting up the goniometer (uglomer) and accelerometer (integrator).

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In connection with this, it is expedient to organize meteorological support in such a way that the meteorological bulletins arrive at the missile units and subunits at not less than one-hour intervals. In such circumstances, the launching of the missile after receipt of the command may, in the worst case, be carried out not later than 50 to 60 minutes afterward, in the overwhelming majority of cases - not later than 35 to 45 minutes afterward.

If there is one field artillery meteorological station (PAMS) in a missile battalion, the existing organization mentioned above is impossible to achieve because a PAMS can process the launching data from only 6 or 7 pilot-balloons with radiosondes, in a 24-hour period. Therefore, it is necessary to increase the capability of the PAMS of every battalion 2 to 3 times in order to permit the issue of a meteorological bulletin every hour.

Nuclear/Missile Armament and Some Principles of Military Doctrine

by

Major-General of the Engineering-Technical Service
M. Goryainov

Universal recognition of the enormous and even decisive significance of nuclear/missile armament, as experience shows, does not exclude various opinions nor even radical divergencies in the evaluation of its influence on armed combat. Divergence of views on the principles of preparing for and conducting modern war, as well as on the structure of the armed forces naturally follows from this.

In the history of the development of armed forces there are many known instances when new equipment (tekhnika), despite its universal recognition, continued to be underestimated for a long time, and did not find its true place in the army. In addition, obsolescent equipment was over-evaluated for a prolonged period of time, thus holding back understanding of the new equipment.

Something of the sort is taking place right now in the introduction of the newest types of armament and in the clarification of their role in warfare. A great number of works and official and non-official studies have been published in many countries, in which the new weapons are evaluated and conjectures are made on their use and on the necessary reorganization of armies.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In this literature it is quite clearly shown that the agonizing process of reorganization is still far from being completed even in rough form, and that there is still insufficient clarity regarding the decisive problems.

Judging by the special literature, everything which is being accomplished in the area of restructuring and reorganization of forces, particularly of ground troops, thus far conforms well with existing, old military doctrines, principles and views on the conduct of battles, of operations and of the war as a whole. Questions regarding the duration of war, its sweep, the enlistment of human masses into the armed forces and the role of the economic potential are all examined in the light of old military theories.

In specific terms, this is expressed in the fact that the new weaponry is for the most part considered as a means of considerably increasing the firepower of the army; therefore, there is basically nothing new from the organizational point of view. A new technical means of combat has appeared - a new arm of troops is created, as was the case with aircraft, tanks, and still earlier, with artillery. The old arms of troops are modernized as much as possible and "assimilate" nuclear charges and missiles. Armies continue to consist of the usual arms of troops (modernized, of course) - plus missile troops.

In other words, the process of assimilating the new means of armament which is now taking place can be characterized as follows: proceeding from the experience of the past and taking into consideration the achievements of the present, armies are adapting nuclear/missile armament to the established views on the preparation and conduct of war.

This is a natural process - blessed by the ages - of an empirical approach to the solution of little-explored problems. Such an approach, which is the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

only possible and normal one for the military science of capitalist countries, is completely unacceptable to the armies of the socialist countries, the military science of which is built on Marxist-Leninist teachings on war. Obviously, we must go faster and further both in the theory of using nuclear/missile weapons and in their production.

However, as is known, there are substantial gaps in our military-theoretical thought - "...in a number of problems we have not shown the necessary creativity, ...scientific boldness and daring, and we have long marked time".[1]

What, in our view, are the reasons why our military-theoretical thought lags behind the practical problem of organizing the army?

The first reason, an organizational-methodological one, lies in the fact that the indispensable minimum of tactical-technical information about the new means - not only ours but also the Americans' - reaches the organizations which carry on military-technical work in extremely scanty amounts. This leads to insufficient understanding of and under-evaluation of nuclear/missile weapons. Together with this, certain technical perfections and modernizations of old types of weapons are more widely known and lead to their over-evaluation under contemporary conditions.

The next reason is more complex. We received our initial information on nuclear means of warfare from American sources. These broadly showed the properties of low-yield nuclear weapons. As far as their potentialities in a full-scale war are concerned, low-yield nuclear weapons (and medium-yield bombs as well)

1. From the speech by R. Ya. Malinovskiy at the All-Army Conference of Secretaries of Primary Party Organizations.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

are primarily operational and operational-tactical weapons. In our view, they are legitimately considered as a means of increasing troop firepower, and the use of them conforms well with previous principles of conducting war. Our own military thought has also lingered more than was necessary on the analysis of the potentialities of low-yield nuclear bombs and, in fact, has not approached the study of the potentialities of powerful, multi-megaton nuclear bombs.

It is clear to all that even 20 kt nuclear charges with missiles call for tremendous changes in the conduct of war and for fundamental changes in the conduct of battles and operations. But the question of what changes follow from the use of intercontinental missiles with charges of 2-5 mgt and even more, remains little-explored to the present time. The first widely published positions on these questions were expressed by N.S. Khrushchev and R. Ya. Malinovskiy in speeches at the January session of the Supreme Soviet of the USSR and later in an address by R. Ya. Malinovskiy to the All-Army Conference of Secretaries of Local Party Organizations. In the light of these widely known statements, we consider it necessary to dwell on some of the characteristics of highly powerful nuclear bombs with TNT equivalents in millions of tons (mgt).

We know from publications of the existence of bombs with a force in TNT equivalents of 1,2,3,5,10 and 20 million tons.

Calculations can be found in American reference books of the combat effects of bombs of 40,50, and 100 million t. In order to be able to imagine the military significance of such means of destruction, we will touch in passing on the potentialities of destruction and annihilation of megaton bombs, about which some materials have been published.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Below is Table 1, which shows the combat effectiveness of megaton bombs in relation to their yield (area is in sq. km.).

TABLE 1

Characteristics	Structures	People			Size of radio-active cloud (sq. km.
Yield in TNT equiv. (thousand tons)	Shock wave partially destr.	Radioactive contamination of terrain			
		up to 500r	up to 300r	up app.100r	
1,000	300	c.1,000	c.2,000	10,000	c.4,000
2,000	-	c.2,000	c.4,000	20,000	c.12,000
5,000	9,000 [sic]	c.5,000	c.10,000	30,000	c.22,000
10,000	1,300	c.10,000	c.20,000	100,000	c.45,000
20,000	3,200	c.20,000	c.40,000	200,000	c.80,000

Note: 1. The table was compiled on the basis of foreign materials.

2. Exposure to a dose of 500r causes death in more than 50 percent of cases; radiation of up to 300r - death of up to 15 percent; the rest lose combat effectiveness for a number of months; doses of 100r cause nausea and vomiting in up to 10 percent of the cases and partial loss of combat effectiveness in the rest.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It can be seen from the Table that megaton bombs raise thousands and tens of thousands of cubic kilometers of radioactive dust into the atmosphere. This dust settles back to earth quite quickly, contaminating thousands and tens of thousands of square kilometers with a lethal concentration and hundreds of thousands of square kilometers with a combat concentration (boyevaya kontsentratsiya). The flash (svetovoye izlucheniye) and the shock wave are devastating only at the moment of action, but the radiological factor of megaton bombs is hundreds of times more important.

As is well known, various shelters protect well against the shock wave and the flash. No shelters can - in practical terms - protect troops from the radioactive substances of megaton bombs, the action of which lasts for many days and weeks, and extends over tremendous areas.

Table 1 shows convincingly that radioactive contamination of terrain by megaton bombs can become the principal factor of combat.

Let us examine more fully the radiological action of a 20 mgt bomb on the basis of testing carried out by the Americans.

In March 1954, on the atoll of Bikini, in the Pacific Ocean, a bomb was exploded with a TNT equivalent of about 15-20 million t. During the explosion, from 30 million t. to 100 million t. of various radioactive particles of earth were thrown into the atmosphere (for 1 t of conventionally exploded TNT, 1.5 - 5 t of earth is not so very much).

As was reported in publications, as a result of radioactive fallout as early as 36 hours after the blast, the cumulative dosage of radioactive contamination in an area of 15 thousand sq. km. reached 900 r, and in an area of approximately 26 thousand sq. km. it reached 670 r.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In an operational situation, 26 thousand sq. km. can be considered as the territory occupied by a front (an area 250-300 km. wide and 80-100 km. deep). We imagine that with the correct exploitation of meteorological conditions, the covering of the territory of a front with the radioactive products of the explosion of one 20 mgt bomb would not only lower the combat effectiveness of the troops of the front, but would also necessitate their abandoning a significant portion of, if not the whole of that territory.

If, as a result of meteorological conditions, the radioactive products of the explosion have the possibility of spreading to an even greater area, then it turns out that in an area of 120-130 thousand sq. km. the level of radiation will be about 200 r, and in an area of 200 thousand sq. km. about 100 r.[1]

Perhaps the figures cited here are only the product of theoretical calculations not based on actual testing. Unfortunately not. Preparing for the testing of thermonuclear bombs, the Americans declared a danger zone in the Pacific Ocean of 130 thousand sq. km. before 1 March 1954. But as is known, Japanese fishermen of the vessel "Fukuryu maru", which was 145 km. from the point of detonation, the inhabitants of the Marshall Islands and American military personnel on the atoll of Rungelap, at a distance of 250 miles (about 400 km.) from the epicenter, all suffered as a result of the explosion of 1 March 1954.

These facts forced the Americans during the repeat tests on 19 March and 22 May to extend the danger zone to 780 thousand sq. km., that is, by six times. Japanese expeditionary vessels which were at sea from May to July established that contamination of water took place in an area bounded by 10° to 18° North Latitude

1. These figures were taken from the book, "Nuclear Weapons and Foreign Policy".

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and 150° to 175° East Longitude, that is, an area of 1,560 thousand sq. km. Two months after the last explosion, the radioactivity of the water at a distance of 1,920 km. from the island of Bikini still exceeded by 20 times the maximum permissible dose for drinking water.

If one takes into consideration the fact that such countries as West Germany and England are about 250 thousand sq. km. in area, the meaning of the residual radiation of one 20 mgt bomb blast becomes clear from all points of view.

In our view, it should be absolutely clear from the above that nuclear bombs of great yield are above all a means of radiological contamination of vast areas with all the resulting consequences.

As was already stated, however, a bomb of 20 mgt is not maximal. If it is found to be advisable, 50 and 100 mgt bombs may be employed.

Before proceeding to further discussion it should be pointed out that usually the characteristics of shock wave and flash are given for optimum conditions. This cannot be said for radiological contamination of terrain. It is known that surface bursts increase the radiological potentialities of bombs, while air bursts decrease them. Nevertheless, test studies indicate that usually 25 to 50 percent of the high-energy particles fall out in the areas of the burst, and the rest, penetrating the high layers of the atmosphere, fall out during the course of many years and cannot have any significance for military purposes.

This means that from the military point of view megaton bombs can be even more effective (by 2-3 times) if optimum conditions for the burst are established from the radiological point of view. In order to do this, it is necessary first of all to know the most advisable heights for bursts. Apparently contact bursts of megaton bombs with a certain digging-in to

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the earth will permit the raising into the air of more radioactive particles, and in such a case more of these will fall out in the area of the burst and fewer will escape into the stratosphere. Besides this, the chemical composition of the ground and soils of the blast areas can also exert a great influence on increasing the effectiveness of the blast products. Such elements as sodium, iron, silicon, and others can substantially increase the radioactive mass of particles which are raised into the air. A firm knowledge of local meteorological conditions in possible strike areas becomes of enormous significance to the proper use of powerful bombs. These conditions should be studied well in advance, and materials should be systematically amassed in such amounts that they would permit a good prediction of the meteorological conditions at any given time.

Let us examine the problem of employing powerful nuclear weapons in operational-tactical situations.

What does radioactive contamination of areas mean to combat formations of troops? As an example, let us examine the effect of bomb strikes in areas which are occupied by combat formations of troops on the defense (Table 2).

Table 2 shows that nuclear bursts will cause death by radioactive contamination for large masses of people dispersed over tremendous areas in the course of a few hours after the bursts. A division which occupies 200 sq. km. is liquidated with one 1-mgt bomb; 4-5 divisions, occupying an area of up to 2,400 sq. km., will lose their combat significance with the strike of two or three 1-mgt bombs or of one or two 2-mgt bombs, during which a large percentage of the personnel may die and the rest will have to be immediately evacuated; a field army (in the USA - up to 350 thousand men) can be liquidated as a military organism with two 10-mgt bombs. At the same time, in addition to contamination, from 4 to 10 percent of the territory (hundreds and thousands of square kilometers) would be devastated by the shock waves and by fires from the flash.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Quantity of bombs needed to create radioactive contamination of fatal and critical concentrations in areas occupied by combat formations of troops in defense.

TABLE 2

Military Unit	Occupied Area in KM^2	Number of Personnel (Authorized TO)	Number of People Per KM^2	BOMBS REQUIRED													
				20 KT		100 KT		300 KT		1 MGT		2 MGT		10 MGT		20 MGT	
				fatal	critical	fatal	critical	fatal	critical	fatal	critical	fatal	critical	fatal	critical	fatal	critical
Division	200	14,000 - 16,000	75 - 80	20	2	6-7	1	3-4	1	1	-	1	-	1	-	1	-
Corps	2,400	70,000 - 90,000	30 - 35	240	10-15	60	4-5	25	2-3	2-3	1	1-2	1	1	-	1	-
Army	23,000	up to 350,000	20 - 25	2,300	100 - 150	500	20-30	250	10-15	20	2	10	1	2	-	1	-

NOTES: 1) As can be seen from the table, the use of bombs with an equivalent of more than 1-2 MGT is not required against formations of troops.

2) The table is constructed from foreign source materials.

1.3(a)(4)

1.3(a)(4)

1.3(a)(4)

[redacted] 1.3(a)(4)

Approximately the same results would be obtained if the combat formations of troops on the offense were examined.

Analysis of the data in the Table from the point of view of effective use of nuclear bombs shows that bombs of large yield are more advantageous than low-yield bombs, both from a combat and from an economic point of view.

Let us examine an example. In order to force the enemy troops to abandon an area of 2,400 sq. km., it is necessary to carry out 240 strikes with bombs of 20 kt yield in the course of a few hours. To launch such a number of missiles in a few hours, it would be necessary to use up to ten troop missile organizations each with 1,500-2,000 men and with 300-400 vehicles of all types. Working under combat conditions, everything else being equal, such a troop organization will suffer losses proportional to the amount of its personnel and equipment.

The same area can be destroyed with only 2 or 3 bombs of 1 mgt or with 1 bomb of 2 mgt. This will be carried out /one or two words missing/ times faster and, under equivalent conditions, with losses smaller to the degree that the number of people involved are fewer and to the degree that they were in firing positions for less time.

It must also be noted that the production of 240 bombs of 20 kt is apparently considerably more expensive than 2 or 3 bombs of 1 mgt.

Does this mean that small-yield bombs are completely unnecessary? No. If bombs of megaton yield, correctly used, are capable of deciding the fates of nations and the over-all outcome of the war, then kiloton bombs will be completely effective for the destruction and elimination of individual targets, for the most part the delivery vehicles (nositel) of nuclear/missile

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

weapons, individual bases, and launching pads. Kiloton bombs will also be needed in operations with strategic goals, particularly when it is necessary to avoid unnecessary victims.

The existing concept that the primary form of using nuclear/missile weapons is the operational-tactical form arose in the army from earlier doctrine on warfare. This form narrows the technical possibilities of nuclear weapons, leads to an inefficient decrease in the yield of nuclear weapons and ultimately makes it necessary to have mass quantities of small-yield nuclear weapons, and hence a large number of ground troop missile units, the effective use of which becomes in itself problematical.

Even today there is a widespread opinion that a nuclear/missile weapon is fabulously expensive, that the basic raw materials used in its construction are obtained with great difficulty and in small quantities. This leads to the conclusion that the economic factor does not permit giving this weapon a sufficiently mass character. In this connection we will briefly examine the following two questions: the understanding of mass quantity (massovost) as applied to nuclear/missile armaments and the cost of nuclear bombs.

What do we mean by mass quantity as concerns missiles and nuclear equipment? This question has fundamental significance in the evaluation of the role of new means of warfare and in the understanding of the nature and peculiarities of nuclear/missile warfare. Nuclear means of warfare are so immensely powerful that a comparatively small number of them can already be considered mass.

If 100-200 atomic bombs can create a turning point in a battle and assure victory, then this number can be considered as mass for a specific goal. If, in order to win a world war, 300-400 thermonuclear bombs are sufficient, then this quantity will also be considered sufficiently mass.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

Therefore, "mass quantity" should be understood not as just any large quantity, but as that quantity which satisfies the requirement or need for it to a definite degree. From this point of view as regards nuclear/missile armaments the concept "mass quantity" will mean that quantity which permits the quality of individual means of armament to be manifested in a decisive manner.

In light of this, the numbers of bombs mentioned above may be considered as "mass" for all practical purposes.

From the speech of Marshal of the Soviet Union Comrade R. Ya. Malinovskiy it follows that 100 2-mgt bombs will turn a territory of up to 500,000 sq. km. into a desert. To inflict utter defeat on a state or states, it is, of course, unnecessary to completely destroy everything. It is important to destroy the important residential centers whose areas comprise not even ten but only a few percentage points of the over-all territory. It follows that the aforementioned 100 bombs are capable of demoralizing the resistance of a state which occupies not 500,000 sq. km. but a great deal more, for example, all the West European NATO allies. In this sense, 100 2-mgt bombs is a sufficiently mass quantity, since the problem of defeating the enemy in Western Europe is solved with this number.

As a result of exercises in the USA during which strikes were delivered against 50 out of 170 typical city areas, it was calculated that these strikes by powerful bombs threatened to liquidate 25 percent of the entire population, up to 50 percent of the means of transportation and up to 60 percent of American industrial enterprises. By analogy with these figures, it follows that 100-120 20-mgt bombs can incapacitate no less than three-fourths of the industry and more than 50 percent of the population of the USA.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Therefore, 100-120 20-mgt or 100-150 2-mgt bombs are the quantity which, if used correctly, will decide the outcome of the war.[1] With this figure we exhaust the understanding of mass quantity for bombs of given yields. To use this quantity of powerful bombs we evidently need a small number of strategic missile troop units.

The situation is different as concerns low-yield bombs. In radiological effect, the above-mentioned number of powerful bombs is equivalent to 100-135 thousand 20-kt bombs. It follows that in the case of such bombs, if the principal aims of the war are to be gained primarily by the use of low-yield bombs, the concept of mass quantity will be defined in many tens of thousands.

Now, regarding the cost of nuclear bombs. In 1954-1955 the production of one kilogram of basic nuclear material (uranium 235) cost about 20 thousand dollars. The total cost of a kilogram of natural uranium was about 100 dollars and a kilogram of heavy water, 65 dollars. Based on these prices of raw materials and on the special features of the production of the first nuclear bombs, it was established that one 20-mgt bomb cost about 100 million dollars. In recent years, important research was conducted on the use of natural uranium together with its isotopes and other fissionable materials in nuclear bombs, which would permit lowering the cost of the bomb to 2-10 million dollars.

In technical literature for the years 1958-1959 there is information to the effect that the cost of nuclear materials, and along with them, the cost of the weapons themselves had significantly decreased.

1. It appears that the liquidation of nuclear/missile bases requires a certain number of kiloton bombs of comparatively weak yield /two or three words missing/... atmosphere.../

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

This gives a basis for supposing that by 1960 the cost of nuclear bombs is within the limits of from several hundred thousand dollars for low-yield bombs to several million dollars for megaton bombs. In 1959 it was reported that a nuclear charge of 3-mgt yield for the Atlas missile is valued at 2-3 million dollars.

This cost is large, in itself, but in comparison with tanks which come to hundreds of thousand and airplanes which cost millions, some of them even tens of millions of dollars, nuclear weapons are comparatively cheap, particularly if the military effectiveness of the two is compared.

From the above it follows that the budgetary capabilities of the largest countries permit the accumulation of nuclear weapons in mass quantities. As concerns missiles there is obviously no doubt that at the present time the status of industry, the availability of processed special materials, the construction-technical level of missiles and guidance instruments permit the organization of mass production of all types of missiles, including intercontinental.

Judging by the foreign press, the cost of missiles in series production is placed at 2.5-5 million dollars for intercontinental, 1.2-1.5 million dollars for strategic, and several hundred thousand dollars for operational-tactical missiles.

All that has been said above about the effects of megaton bombs, about economic and productive capabilities, permits us to come to the conclusion that the nuclear/missile weapon has become (or can become) a mass weapon, and its destructive, and in particular its radiological characteristics, are actually capable of creating conditions in which the fundamental object of the war - the destruction of the enemy - can be accomplished technically in a short period of time and without overtaxing the economy of powerful industrial countries.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

We believe that a view of contemporary warfare, of prevailing military doctrine and of the principles of organization of the armed forces must differ radically from views of war, not only of the pre-atomic period, but also of a war in which the operational-tactical use of low-yield nuclear/missile weapons plays the leading role. Proceeding from this, we will examine the following questions:

- the time limits (limit of duration) of a nuclear/missile war;

- the nature of the course of the initial period of war and the tasks of the armed forces in a nuclear/missile war;

- the principles of the organization of the armed forces.

The time limits of a nuclear/missile war. The history of mankind recalls wars of various durations, up to hundred-year wars. The duration of wars depends principally on the sharpness of the contradictions and the economic and technical capabilities of the warring sides. The question of the permissible time limits of a war had no decisive significance in the past. The means of warfare, the means of destruction were essentially so small in comparison with the creative capabilities of mankind and of nature that the thought of the possibility of monstrous destruction and mass annihilation of people never arose.

The question is posed differently today. It is clear from the above-mentioned considerations that if the number of nuclear weapons sufficient to liquidate human life on earth has not yet been created, it can be created in the immediate future. In this connection, the most destructive factor is radioactive contamination.

However, the process of radioactive poisoning of the atmosphere and the earth's surface cannot be

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

instantaneous. This process can take place in a certain span of time. Consequently, the time span from the moment of the beginning of a nuclear world war to the moment of the poisoning of the atmosphere of the globe (or a given zone of it) with a concentration of radioactive substances dangerous to human life on earth can be called the time limits of a war.

The ultimate limit of a war depends on a series of factors, namely:

- the scientifically determined limit of concentration or radioactive substances in the atmosphere;

- the quantity and quality of the nuclear devices detonated;

- the intensity of the nuclear bursts;

- the height of the bursts and their distribution over the surface of the globe, and on certain other factors.

We will not examine the above-mentioned factors in detail. For the goals of this work it is important to show that the scientific solution of the question of the time limits of war is an absolute necessity.

Obviously, the basic solution of this question depends on the definition of the maximum permissible dose of atmospheric contamination. Kissinger's book, "Nuclear Weapons and Foreign Policy", states that a doubling of the natural dose is required to eliminate all life, which can be achieved in the northern hemisphere by 300-800 50-mgt bombs or 750-2,000 20-mgt bombs. This number of bombs can evidently be built by even one state.

What conclusion should be drawn from the arguments on the time limits of a nuclear/missile war, if such a war is thrust on us? There can be only one. The main decisive phase of the war, defined as the complete

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

paralyzation of the enemy's nuclear strength, must be achieved in the shortest possible time; this must be much shorter than the time necessary to create a dangerous radioactive concentration. The technical possibilities for such a solution are evidently available.

A protracted nuclear/missile war with a decision in favor of one side is excluded because such a war on the strength of military logic, as past experience teaches, must be waged with increasing severity and with the use of ever more powerful and ever more numerous destructive nuclear weapons. The result of such a course of war would be equally disastrous for all warring sides.

A decision in favor of one side depends on readiness and ability to finish the war in the shortest possible time. A great deal has been said in our press recently concerning the fact that even the bourgeois military ideologists reject the theory of a short-term nuclear-missile war. Such statements have, in fact, been made in the West. But this cannot serve as a serious argument in favor of a prolonged nuclear/missile war.

Prior to the appearance of nuclear armaments, representatives of Western military thought created a large number of theories about short-term war, about blitzkrieg. It is well known that Hitler's military doctrine was based on this. Such blitzkriegs were particularly alluring against countries with inadequately developed industry or with comparatively small territory. Capitalism was deeply interested in such an approach to war because an extended war accompanied by arming of the masses in our time would very probably lead to revolutions. The experience of two world wars has already shown that both wars were prolonged and protracted. The principal reason for this phenomenon could be formulated thus: comparative equality of forces, means and potential capabilities of the warring sides in the course of a certain segment of time under conditions of comparatively weak means of warfare (destruction).

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Is there anything new in this question of nuclear/missile weapons? Evidently, yes. The material base for a war lasting for years may not even exist, considering contemporary means of destruction, which substantially (by a large factor) exceed the means of creation.

How are these new conditions reflected in the interests and the ideology of the warring classes?

First of all, one must keep in mind that no normal man can be interested in the destruction of mankind. The matter is different, however, from the point of view of the ruling classes who are disappearing from the scene of history.

History has shown more than once that a dying class, a dying social order, gives birth to theories and dogmas of human destruction characterized by the phrases "apres moi le deluge" and "better be atomized than communized". For reactionary forces, doomed to perish by dint of historical hopelessness, a long war (like any other war) is not contraindicated, the more so since preparation for such a war is economically advantageous for certain monopolistic circles.

Preparation for an extended war is many times more costly than for a short war and the profits of capitalists many times higher in this case. Preparation for an extended war is conducted on the basis of the theory of maximum application of the country's economy to the needs of war and requires expenditures on all other forms of armament and other requisites of a long war as well as on nuclear/missile weapons. This facilitates an increase in the concentration of capital and in the monopolistic power of certain groups. But from the point of view of the cost of the military machine and its combat effectiveness, the nuclear/missile weapon is the cheapest and a short nuclear/missile war is relatively the most economical in expenditures on the forces of destruction. And if the nuclear/missile

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

weapon, in reducing the duration of war, reduces the incomes of the monopolies, then the pertinent groups of monopolists will, of course, be for a long war.

Therefore, as a result of economic reasons and partly because of the aspirations of groups connected with military production to preserve the commanding position which they hold in the economy of a country like the USA, the theory of an extended war receives wide circulation. This theory ties in well with the necessity of keeping colonial and economically weakly developed countries under the threat of war and even to thrust wars upon them.

The interests of the progressive forces of the world dictate a different approach. The material prerequisties for the victory of the socialist world over the capitalist world by peaceful means have already been created. Consequently the progressive forces are keenly interested in avoiding war. But if war becomes inevitable, the new world, naturally, must strive to keep war losses to a minimum and consequently should do all possible to keep the war short and, in any case, to finish the decisive phase of the war prior to substantial atmospheric contamination over large areas.

The nature of the course of the initial period of a war and the tasks of the armed forces in a nuclear/missile war. In examining these questions we start from the proposition that the leading capitalist states are preparing for a nuclear world war, in which they will strive for a decisive result at all costs. In technical times, such a decision means the inevitable use of the most powerful nuclear and other weapons against which the other side must use no less powerful destructive weapons within certain time limits to gain the victory.

Before the age of nuclear/missile armaments it was considered that the direct manifestation of war was armed conflict between two opposing armies of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(

[redacted]

1.3(a)(4)

peoples, of states, or of social classes. Contemporary technical means of warfare, as N. S. Khrushchev pointed out, dictate a different concept of the physical process of war itself. For a number of economically powerful and heavily populated states which are, however, small in territorial size, the war can end in their complete defeat and even destruction before the main part of the armed forces of these countries can enter into action. For the USA, the situation is somewhat different. The disruption of their potentialies for resistance will require more time and weapons and, obviously, it will be difficult to avoid some strikes from their side. In these circumstances, strikes in the enemy's industrial rear, and on his political and administrative centers acquire an overwhelming significance. Powerful strikes, capable of disrupting (or liquidating) the economy and the organized control of the country and the army, will naturally undermine the base of military activity and the existence of the armed forces.

Concurrently, strikes must be made on the necessary number of strategically active (or potentially active) targets (bases, launching pads, naval vessels) from which the enemy can launch nuclear weapons at our economic and political centers. In these cases, the strikes could be made with bombs of lower yields. Given the selection of the appropriate bomb yields and their technically correct use, it is possible to indicate tentatively the quantity of nuclear weapons required. We realize that defining our views on just this point in concrete terms can be most vulnerable for a number of reasons. But the importance of the problem demands this concrete definition, it requires a point of departure. In our opinion, even a mistake of 2-3 times in this case should not be embarrassing; it is important to show the possible nature of the process based on actual material.

Analysis of data published in foreign literature indicates that for a world war about 200 bombs from 1-2 mgt to 15-20 mgt and about 600-900 bombs from

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

10 to 30 kt (for strikes on nuclear weapons targets, if there are 300 as is reported in the press) are needed.[1]

It would seem that a total of 1,000-1,100 nuclear strikes are not many for a world war and all these deliberations may appear to be unfounded. However, it should be remembered that a similar number of strikes (chiefly by hydrogen bombs of the type detonated at Bikini) is capable of creating radioactive contamination (higher than 600 r) of an area of about 2 million sq. km. and contamination of over 50 r of an area of about 20 million sq. km. (This does not allow for the enemy's detonations of nuclear weapons.) Moreover, hundreds of thousands of kilometers will be devastated by shock waves and flash radiation. This fact necessitates a very careful approach to the use of megaton bombs in general, and particularly in Europe, where population density is extraordinarily high.

Apparently, however, the use of nuclear/missile weapons under technically optimum conditions may not require such a quantity of megaton bombs for destruction of the NATO bloc.

Therefore, it appears that just a few hundred powerful nuclear bursts will be the primary and decisive factors affecting the outcome of the war and that they will be made in the first hours and days of the war. It follows that the initial period of a war becomes its decisive period, the period in which the armed forces solve the primary technical problem of the war - to liquidate the enemy's capability to use nuclear/missile weapons, to undermine his will to fight and to weaken decisively his forces and means.

1. If enemy atomic targets are greater in number, or if these targets are specially concealed, then the number of small-yield bombs can be increased somewhat. Such an increase on the radiational situation in the world .../two or three words missing/.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

The second period of war, undoubtedly protracted in time, will evidently consist of liquidating the resistance of military organisms still extant, of rendering immediate all-round aid to victims and of reconstructing the economies and state systems of the appropriate countries.

In this period, considering the scale of destruction, reconstruction work will require extended and enormous efforts by the socialist countries and the enlistment of large masses of peoples, possibly numbering in the millions.

It appears that during this period, the principal role will be played by the ground troops, aviation, and navy.

One can proceed from a different concept, according to which the primary tasks of a future world war will be resolved by ground armies on fronts in coordination with strategic missile troops, aviation, and the navy; to achieve victory it is necessary to destroy the enemy's armies and to occupy his territory; strikes by the strategic missile troops deep in the enemy rear will play an important but subsidiary role. This would mean that we underestimate the potential of powerful multi-megaton nuclear bombs and of long-range missiles, that we will have to create tens of thousands of low-yield nuclear bombs, form a large number of operational-tactical missile units, maintain various mass types of troops and a multi-million man army, and base all plans on an extended war with the inherent consequences of economic overstress and of losses many times greater than the losses of World War II.

A third concept is also possible. Keeping aside, in a technical and practical sense, the principal and decisive role of strategic missile troops, to maintain powerful ground and interacting and inter-dependent air and naval forces, which, like the ground troops would be saturated with operational-tactical missile units and constantly perfecting (by type of troops) their combat and auxiliary equipment.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

This is a cautious concept calculated to finish the war in the shortest possible time, but if unsuccessful in this, to be prepared to wage an extended war with the maximum efforts of all the forces and means of the country and of coalitions of countries.

Past experience teaches us that at the beginning of all great wars, the opponents seriously overestimated their own strength and underestimated the enemy's strength. Moreover, not a single war ever went the way it was planned.

It is possible that in the course of a war a situation can arise in which the strategic missile troops of both sides will turn out, for various technical reasons, to be not entirely reliable, that they will only partially fulfill their tasks, and that the decisive effect will not be achieved. In this instance, during the time period necessary for the restoration of the combat capability of the strategic missile troops for the Eurasian war sector, the role of the ground troops and of aviation will become decisive. The role of the navy will also increase, particularly that of submarines. From this point of view, the third concept appears to be the most acceptable, despite the fact that it leads to a substantial increase in the burden of expenditures prior to the beginning of war and presupposes an even sharper increase with the initiation of war.

At the same time, if war is thrust upon us, we must be so prepared that the strategic missile troops can send sufficiently powerful strikes in the first minutes to paralyze the enemy countries and armies and to deprive him of his nuclear/missile weapons. The operations of the other types of troops during the initial period of war must be coordinated with the operations of the strategic missile troops and be subordinate to them.

[redacted] 1.3(a)(4

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

From all that has been said it is obvious that the nuclear/missile weapon is primary and decisive in the present period fo time; for this reason the strategic missile troops have become the primary and decisive type of troops, with all the consequences ensuing from this fact. The situation is somewhat different as concerns the quantitative side of the question. The primary and decisive type of troops need not be and indeed will not be the most numerous. The ground troops and the PVO troops will be more numerous.

The new means of warfare, as was said earlier, bring upon the scene other types of troop formations - medical-sanitation and reconstruction formations - which have every reason to be mass formations, and to be formed and undergo training on territorial principles. In our opinion this question requires very profound investigation.

Until the recent past, ground troops were legitimately considered as the primary type of armed forces, since they carried out the principal tasks of war, which amounted to the total defeat of the enemy's armed forces and the taking of his territory. Now, when the forms of war are changing and its principal tasks will evidently not be decided on fronts in direct engagements of opposing armies, but rather in the interiors of countries, the ground troops cannot carry out the principal task of war independently.

In addition to the usual resources of combat materiel, the ground troops have missile equipment with a limited radius of operation. With these means of armament, the ground troops can neither withstand the strikes of strategic missile troops nor protect the country from these strikes. At the same time, the ground troops must be regarded as forces which, together with the air forces are capable of assuring victory in all circumstances.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Taking into account the possibility that megaton bombs may be used on the battlefield, it is necessary to make an all-round evaluation of the existing organization and the current combat formations of ground troops and of their suitability for nuclear/missile war.

As history teaches, the combat formations of troops and the corresponding organization of troops change form depending on the means of combat, and primarily on the decisive means, firepower. The more effective the fire means of war, the more profound the changes. Right up to the appearance of nuclear/missile weapons, to the degree of the strength of fire, combat formations have grown more and more deeply.../two or three words missing/.

The tendency to thin out military formations has increased in the past five years under the influence of nuclear/missile operational-tactical weapons, but contemporary organization of troops (preserved from the pre-atomic period) and under-evaluation of the new conditions of conducting war fetter and retard this tendency.

It appears that combat formations of ground troops can become sufficiently vital and combat ready through fulfillment of the following conditions:

- increasing the combat independence (autonomy) of all organizational levels (zveno) of troops, and particularly of the lower - the tactical ones;

- increasing the firepower of tactical elements of units and large units;

- substantial increase in the speed of moving of troops;

- a sharp thinning out of personnel and equipment in combat formations.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

Increasing the combat independence of all levels (zveno) of the troop organism is possible by weakening or eliminating the mutual dependence in combat (but not cooperation) between organizational elements (yedinitsa) of troops. The principles of standardization of the means of combat and auxiliary equipment, of organizational autonomy and of a broad independence in carrying out combat missions, must underlie army structure from the primary cells (yacheyka) through all succeeding levels.

Organizationally, it appears advisable to create units (chast) composed of interchangeable, uniform, primary tactical elements (yedinitsa). The creation of regiments of ground troops composed of elements which have high firepower, are completely mobile, tactically independent, and low in personnel composition, and which in case of loss can be easily replaced by similar ones, must have a positive effect on the viability of combat formations.

An increase in speed of movement can be achieved by full mechanization of troops, which would increase this speed by several times in cross-country, as well as in road, movements. Movements of large combat groups of ground troops by aircraft must become common and be applied in the very broadest dimensions.

* * *

Existing military doctrines are built on the following basic principles:

- a country's entire economy and the country as a whole prepare for war beforehand;

- calculations are based on a protracted war and on mass armies which will enlist the greatest possible number of the healthy male and female population;

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

- victory or defeat in war is decided on fronts of opposing armies; the strength of armies is determined in the final analysis by the viability and power of the rear;

- the theaters of military operations are studied from the standpoint of the decisive significance of frontal combat of armies, and in this connection, plans for achieving war aims are worked out which take into account the factors of time, space, forces and means; the capabilities of enemies and allies are studied in this same manner;

- military operations are based on principles of seizure of the initiative, concentration of maximum forces and weapons on the main axis, on the selection of the most advantageous time for initiation of operations and for delivery of the main strike;

- the achievement of the basic goals of war absolutely presupposes the total defeat or destruction of armies and the seizure of the most important parts or all of the enemy's territory.

In light of the new quality of nuclear/missile armament it can be said that the above-listed principles of contemporary military doctrine are subject to radical review. Some of the principles will lose their significance entirely, others will take on a different content.

New doctrines must be built on the basis of the potentialities of mass nuclear/missile and radio-electronic means of warfare. Their principles must reflect a new approach, a new understanding of the dimensions of time, space, destructive forces, and forces of resistance.

The new military doctrines must proceed primarily from the principal and decisive role of nuclear/missile strategic weapons in war, and, consequently, from the principal and decisive role of the type of troops armed with these means of combat.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Basic principles of the new doctrine could include the following propositions:

- the contemporary power of the forces of destruction is immeasurably greater than that of the forces of creation;

- the nuclear/missile weapon is a mass type of weapon, is relatively economical, and, from the combat point of view, it is the most effective;

- the range of nuclear/missile weapons ensures their reaching any point on the globe; in this connection, their accuracy satisfies practical requirements;

- the theater of military operations is the entire globe;

- the primary task of the armed forces in war (from our point of view) should not be the seizure of territories, but of depriving the enemy of the possibility of using nuclear/missile weapons; in case of necessity, temporary occupation is permissible;

- a nuclear/missile war must be short-lived; its active phase can be measured in days or weeks;

- the time limits of a war must be determined by the power of the nuclear weapons, and the intensity and number of bursts which will not cause a dangerous saturation of the atmosphere and of the surface of the globe or the expanse of our country, or allied and non-combatant countries, with radioactive substances.

In our opinion, investigation of the questions connected with the elaboration of military doctrines and a discussion of them within definite limits must be considered the most vital necessity for contemporary military thought. It is in this light that the present article offers itself as a means of posing the question. Moreover, it seems to us that the time has come not only to exchange views on these questions through articles in journals, but also to cooperate in every way in the creation of fuller works.

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Most Urgent Problems of Training Command Personnel and of Increasing the Combat Readiness of Border Military District Staffs", written by Major-General A. Klyukanov.

This article appeared in the 1961 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1961 First Issue of Military Thought was sent for typesetting on 22 December 1960 and sent to press on 13 January 1961. It is distributed only within the Ministry of Defense down to the level of Army Commander.

The Most Urgent Problems of Training Command Personnel and of Increasing the Combat Readiness of Border Military District Staffs

by

Major-General A. Klyukanov

Timely proposals have been appearing in the pages of our military press with regard to the improvement of the methods of operational training of generals, senior officers, and staffs. We believe that, in addition to the problems advanced by the authors of a number of articles, the necessity has arisen to examine ways of qualitative improvement of the organization of the training of troop command personnel of border districts with the aim of bringing it even closer to the operational assignment of troops and to the conditions which the generals and officers will meet in a real situation of the initial period of a war.

The maintenance of the constant combat readiness of our Armed Forces in order to strike, if the necessity arises, an immediate and crushing blow on the enemy, demands from generals and officer personnel a continual and comprehensive theoretical elaboration and a practical fulfillment of a whole series of most important measures.

The command personnel of border district troops, who will be the first to engage in battle, must pay particular attention to working out measures for training troops for swift combat action directly out of concentration areas along definite operational axes.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

As is known, the concept of combat readiness of troops includes a number of factors, including the following decisive one - the comprehensive theoretical and practical preparedness of generals and officers and of their organizational ability. The higher the level of the theoretical training and of the professional and political qualities of officers and generals, the higher the degree of combat readiness and combat efficiency of the troops and staffs.

In order to be prepared for immediate combat operations along the probable operational axes envisaged by the plan of operation for the initial period of a war, the basic troop command personnel of border military districts and armies (by the latter we have in mind Military Councils of armies and the command elements of line large units) must know the operational assignment of the formations and large units.

Unfortunately, commanders of large units and commanders of armies do not know the specific combat tasks which they must fulfill in the course of the initial operations. This may lead to a situation similar to the one quite well known from the sad experience of the initial period of World War II, when, as a result of the staffs' loss of control of operational formations, some commanders of large units did not know what to do during the surprise offensive of the German-fascist army.

In modern conditions of warfare, with the widespread use of nuclear/missile weapons, it will be difficult, in the event of a short threat period, to accomplish combat tasks to work out and organize the total sum of measures for repelling the enemy offensive, and it will be completely impossible to implement practical study of the directions designated for the conduct of troop combat operations, of specific lines, and of objectives on them.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

If we assume that there will be no threat period and that the enemy, by sudden massed strikes of nuclear/missile weapons, aviation, and other means of attack, will unleash a war and will disable some higher staffs, then the importance and acuteness of the need for advanced (even in peacetime) transmission of their operational assignments, even if only to commanders of line large units and commanders of border armies will increase many fold, as will also the study of the probable directions of their combat operations.

Undoubtedly, strict secrecy must be observed in the study and elaboration of these important problems which have great State significance. To these ends, it is necessary to think through and carry out a whole series of measures in order that the entire operational plan for the initial period of a war along a given direction remain secret.

We believe that staffs of military districts should organize one or two special exercises a year for commanders of armies and commanders of line divisions, with a view to raising the readiness of the basic troop command personnel of border military districts to assume immediate control of units and large units of first-line readiness in their movement directly out of concentration areas on predesignated axes and in their commitment to battle. In these training exercises and studies, there should be an elaboration of the measures dealing with the organization of troop combat operations in accordance with their real operational assignments.

To these same ends, it is desirable to conduct special tactical rides (polevaya poyezdka) along probable axes and lines of troop movement in initial engagements, both on the territory of the Soviet Union and on the territory of the bordering peoples' democracies. Our border military districts, as is known, are located at various distances from the national borders of capitalist countries. Consequently, the conditions for conducting combat operations during a

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

surprise attack by the enemy will be different for the troops of different districts. Some will have to operate independently from the territory or on the territory of the Soviet Union. Others, in all probability, will engage in battle in coordination with armies of the countries of the Socialist Camp either on the territory or from the territory of these states. In our opinion, the above-mentioned circumstances explain the great importance of careful advance study by command personnel of concrete operational axes in their areas.

In recent years, during command-staff exercises on the ground dealing with the initial period of a war, a provisional national border was usually established deep within the territory of our country. Staffs were concentrated and provisional groupings of our troops and of probable enemy troops were created behind this provisional border. The execution of combat operations of the antagonists was carried out in the zone along the provisional national border and then to either side of it (in the direction of the actual border or into the depth of the country), but always on the territory of the Soviet Union. The training goals of these exercises were fulfilled but removed to a certain extent from the actual situation in which troops find themselves in peacetime and from those concrete tasks they will have to fulfill in the first days of a war.

Of course, such exercises are highly useful for the numerous staffs and for the generals and officer personnel participating in them, and it is extremely necessary to conduct them in the future. However, along with such exercises, command-staff exercises under conditions existing in the border territory should be conducted for a limited number of troop command personnel of border military districts.

In accordance with instructions of the Minister of Defense in his directive on operational training for 1961, it would be an extraordinarily useful method of

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

training troops and staffs to have a series of exercises and group exercises which would begin with placing staffs on combat alert and with their transfer to the established concentration areas.

In such exercises and group exercises, the possible nature of the combat operations of the probable enemy's army should be studied not only from the point of view of his approach to methods of surprise attack and to the conduct of combat operations in general, but also with regard to those probable tasks which enemy troops may have in the engagements of the initial period of a war. In connection with this, it is necessary to take the grouping of our troops, border armies, and military districts actually existing at the present time with their actual composition, TOE, number of large units, units, and the areas of their actual concentration.

In the plans for these exercises, it is essential to reflect the concrete conditions of the disposition of the troops of a border military district, the probable nature of the operational situation and the tasks of formations and large units, not disclosing by this, of course, the real operational plan.

For example, the troops of the border Odessa Military District are deployed at a distance of 700-1,000 kilometers from the coastal borders of countries of the aggressive military bloc (Turkey, Greece). The probable enemy plans, by means of a surprise launching of nuclear strikes by missiles, aircraft, and naval forces in this direction during the initial period of a war, to destroy or annihilate the vitally important administrative-political, economic, and military centers of Albania, Bulgaria, Rumania, and of the southwestern oblasts of the Soviet Union and, by a simultaneous invasion by ground troop groupings deep into the territory of

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

the socialist countries, to seize the most important objectives and to rout the basic army troop groupings of countries friendly to us.

It is to be expected that the enemy will assign his troops the mission of destroying, by means of nuclear/missile strikes, or of capturing, by means of dropping airborne forces and by operations of mobile units of ground troops, the existing crossings over the Danube River and other water barriers and also the basic passages across the Eastern Carpathians and Transylvanian Alps, in order to cut off and isolate the troops of Albania, Bulgaria, and Rumania from Soviet troops.

In such conditions, it seems essential to us that the basic command personnel of a district and the personnel of its large units study the following problems in the system of operational and command preparation; the organization and the conduct of marches over long distances; the crossing of water lines, mountain passages and passes under conditions of enemy counteractions; the organization and conduct of meeting engagements as the most typical form of troop combat operations under the conditions of an invasion initiated by the enemy; the organization of capturing and holding advantageous lines until the second troop echelons, mobilized at the beginning of a war, are brought up; the problems of the organization of coordination with the armies of the peoples' democracies; measures for materiel, technical, and medical support, and other problems.

In the example under consideration, district troops may encounter particular difficulty in the organization and conduct of regroupings over considerable distances with an exit, if such is required, for example, into the territory of southern Rumania and Bulgaria. The fact is that during the conduct of a regrouping by combined methods (units move on their own on wheeled transport and tracked equipment is transported by rail), approximately

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

twice as much time is demanded for complete concentration of troops than if they had completed the march exclusively under their own power. The difference in width of railroad gauge in the USSR and in Rumania and Bulgaria requires additional time for transloading tanks and other tracked equipment, by dint of which tanks will not be able to take part in combat operations simultaneously with their units and large units which completed the march by motor vehicle. We consider the best method of regrouping under conditions of nuclear/missile war to be the simultaneous movement of units and large units under their own power. To this end units of the Odessa Military District, for example, are conducting appropriate studies to increase the cruising range of wheeled and tracked vehicles to 1,000-1,500 kilometers by adding to the amount of fuel contained in the vehicles.

Measures for combat, engineer, materiel-technical and other types of march support will require the most serious attention, and they need, in our opinion, further study and clarification during the exercises and group exercises proposed by us. It seems necessary to us, in this connection, to solve all problems of the planning of regrouping and of the conduct of our troop combat operations in coordination with the Rumanian and Bulgarian armies.

We have dwelt in detail on one example in order to show how important it will be, in our opinion, to conduct operational training of command personnel of border military districts under conditions as close as possible to the probable nature of military operations in a given operational direction. Such training, carried out in advance in peacetime, will resolve a large number of problems of a theoretical nature and will fulfill practical preparatory measures of organizational and technical procedure.

It is perfectly obvious that with attentive examination in each border military district, a special list of problems, questions, and measures

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

will arise which must be solved in accordance with the given conditions of the theater of military operations and with local peculiarities.

The Armed Forces of the USSR have good experience in strengthening friendly contacts and in organization of coordination with the armies of the Warsaw Pact countries, and also in the study of the general principles of combat operations from the command-staff and other exercises to which command personnel and some staffs of formations of the armies of the peoples' democracies are invited. Unfortunately, this experience is not shared even with a limited number of generals and senior officers of the Soviet troops deployed in the border military districts who, in case of war, must personally direct combat operations of their troops in coordination with the troops, and on or from the territory of the countries of the Socialist Camp.

For example, in the practical conditions of the Odessa Military District, for raising the combat readiness of large unit commanders and of the command element of operational formations, and with the aim of establishing coordination, strengthening friendly ties, and becoming familiar with the armies of Rumania and Bulgaria, for the study of the terrain, probable lines of combat operations, water obstacles, mountain passages and passes, road conditions and other peculiarities of the theater of military operations, it is highly expedient to assign command personnel periodically to exercises of troops and staffs of the peoples' democracies, to organize field and military-historical trips, tourist trips, and excursions, to send generals and senior officers for rest periods to the sanitoria of these countries, and to utilize other possibilities. All this will contribute to the careful study of the theater of military operations and of actual operational axes.

Under modern conditions the small peacetime composition of the ground troops of border military districts will be reinforced, if the situation demands,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

with large units and formations by full mobilization of the latter. These complex and responsible tasks, naturally, must constantly be the cynosure of attention of the command personnel and higher staffs. In light of these demands on the command-staff exercises proposed by us, it is necessary to explore all aspects of the organization of troop control of a border military district connected with the difficulties of simultaneous solution of two problems: the conduct of combat operations and the full mobilization of troops. Thus, in the peacetime composition of troops of a military district there are line divisions (of increased combat readiness) and divisions of reduced strength. The field command of an army, army units, and front units are also kept at reduced strength. It is natural that the line divisions, after concentrating in their areas as a result of combat alert, will initiate a march to fulfill combat tasks, and that divisions of reduced strength, army units and supporting subunits of army headquarters will begin full mobilization.

Therefore, the commander and the field command of an army must assure firm control of large units on the march and of their combat operations in the event of deployment for engagement with the enemy and, simultaneously, to direct the conduct of full mobilization. In this connection, the distance between the large units executing a march or engaged in battle and the areas of full mobilization, will increase continually. This is why it is necessary to work out right now methods by which a reduced strength headquarters with limited means of communication could assure uninterrupted control of troops until the completion of mobilization and the bringing up of fully mobilized units and large units to the area of combat operations of the first echelon of the army.

Therefore, problems of the organization of troop control of border formations in the course of the first operations of the initial period of a war demand urgent study and practical assimilation.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Without question, the mastery of practical measures for full troop mobilization is connected with the removal of people and equipment from the production of material wealth. This is an expensive measure for the State and it is, therefore, undertaken very rarely. At the same time, the demand for full mobilization of various large units within the shortest time is especially important for the formations of border military districts, because the speed of buildup of first-echelon troop strength, consisting of a limited number of divisions of increased combat readiness, will depend on the period required for fully mobilizing large units and units of reduced strength, of which, as a rule, the second echelons and reserves of armies will be created.

As is known, the military leadership of the imperialist states is planning in advance to launch nuclear strikes in the initial period of war, against the most important administrative-political centers, with the aim of disorganizing control and disrupting the mobilization and buildup of the armed forces of the countries of the Socialist Camp. These intentions of the aggressive circles must be considered in our mobilization preparations and work.

In our opinion, it is necessary to organize joint special exercises of the basic command personnel of the troops and of military commissariats. In these exercises we should work out and investigate a whole series of measures directed primarily at:

- the maximum curtailment of the time required for full mobilization of the troops;

- the protection of the personnel, motor transport and other equipment withdrawn from the national economy for the mobilization and buildup of troops, from nuclear strikes and other enemy means of mass destruction;

- the creation of conditions for stable and uninterrupted control of the process of full mobilization.

1.3(a)(4)

The above-mentioned problems of improving the training of generals, senior officers and of the readiness of the staffs of border military districts for control of troop combat operations do not encompass the whole range of tasks, in support of troop combat operations, which must be fulfilled by operational formations and large units on their entry into engagements of the initial period of a war directly from concentration areas and of full mobilization along designated directions; however, they are, in our opinion, most important in the problem of increasing the combat readiness of our border district troops.

Certain Questions of the Control of Troops in Modern Operations

The nuclear/missile weapons and other achievements of science and technology have served as a basis for the further development and improvement of the theory of military affairs, and of the equipping and organizational structure of the troops. As a result of the changes which have taken place in the nature of modern operations, the combat capabilities of the types of armed forces and arms of troops are basically different from the operations and the combat possibilities of troops during the period of World War II. The substance of these changes has already been mentioned in our press.

All this has complicated, to a great degree, the direction of the combat activities of troops and has demanded of the organs of control more precise and coordinated work, ensuring swift reaction, flexibility, and combat efficiency in troop control.

It is evident that under such conditions of armed combat it is of the greatest importance to have more perfected forms and methods of troop control, utilizing all the latest achievements of science and technology, especially those of electronics, telemechanics, and automation. With this purpose in mind it is necessary to improve considerably the organizational structure of staffs and their technical equipment, especially in view of the fact that staffs have undergone virtually no changes in the organizational sense since World War II.

The experiences of World War II and practice in postwar exercises show that the commander's skill in directing troops depends, to a large extent, on his

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

ability to find the correct forms and methods of control that would best answer the nature of the armed conflict and would fully conform to the situation. It is considered that the most favorable conditions for uninterrupted and firm control of troops was secured for the commander at the primary command post. However, despite all the positive qualities of this control organ, it was, and continues to be, unwieldy, with a large number of persons directly subordinate to the commander and having many channels in the work.

All this artificially complicated the coordinated and exact work of all elements of the command post, it burdened the commander's activities with secondary, and sometimes insufficiently coordinated, matters and distracted him from thoughtful, well-rounded analysis of the constantly changing situation and making timely decisions. In some commanders this bred indecision, lack of initiative, and the inability to make a courageous and correct decision quickly, based on a thorough knowledge of the developing course of events. As a result the commander was forced to resort to systematic briefing by all his commanders, in the course of which he became familiar with the situation and made a decision.

A similar method of work by commanders and staffs took a lot of time, and often troops did not have time to prepare for impending actions. If in the past this did not lead to appreciable results, then in modern conditions this practice has completely outlived itself and can have a fatal influence on the course and outcome of a battle and an operation.

In searching for more perfect forms and methods of control, wide dissemination was given to the practice of controlling troops by an operational group, small in composition and headed by a commander who guided the activities of the group in accordance with the given situation. The advantages of this method of control consisted of the fact that the exact and

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

coordinated activity of a well-trained and efficient operational group which, besides the commander, had only a part of the directing staff immediately connected with control, ensuring flexibility and operational efficiency in making quick decisions, and briefing the troops on their missions in a timely manner, excluding the many stages and loss of time for various coordination. The fact that combat and operational documents were produced in a brief and clear form, without unnecessary details, warrants attention. Often battle orders and instructions were written directly from the commander's words, then were graphically plotted on maps, and less often were put out in the form of written documents. The missions of the troops were given orally with subsequent written confirmation.

The operational group had high mobility and the ability to deploy and redeploy secretly. All these advantages became evident in a clear and obvious form when controling tank and motorized troops during the years of the past war, whose experiences can greatly influence the further improvement of forms and methods of troop control.

However, we consider that the plain transfer of experience in the control of troops with the help of operational groups will not ensure a solution of all the most important problems that confront the organs of control in modern operations. Besides, it should be taken into consideration that often these operational groups replaced the staff as a whole, actually removed it from the direction of combat operations. It seems to us that the principle -- the commander carries out control over the troops personally and through his staff -- should remain unchanged, and that the commander is obligated to rely on his staff to an even greater degree.

The role of the staff, as the basic organ of the commander for ensuring firm and constant control of the troops, has grown significantly. In relation to

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

the staffs of the various arms of troops, it is the highest staff, and during the organization of coordinated work its directions must be received for strict execution.

As a result of this the role of the chief of staff also increases. He concentrates in his hands all the results of the many-sided and coordinated activity of the whole staff and must be ready /four or five words missing/ essential information to the commander, for making a quick, well-founded decision and to ensure that the troops are informed of their missions in a timely manner. All this will relieve the commander of the need to listen to a large number of commanders and will immeasurably raise the role of the staff as the only operational organ headed by the chief of staff, who is, at the same time, the deputy commander.

It is apparent that the existing organization of the staff does not fulfill modern requirements, because of its unwieldiness, its many channels, and lack of operational efficiency, and that it is in need of basic improvements. In order to avoid improvisation, which can be observed now in exercises, we propose that a permanent (under combat conditions) organ for direct management of troop combat operations be created on the base of the field command of a front (army), which would have a harmonious organizational structure. It would be limited in composition, flexible, mobile, and adequately operational. The basis of this organ has to be composed of part of the operational and intelligence directorates (departments), of the combined-arms staff and the staffs of the arms of troops and types of armed forces. Such an organ, detached from the field command and called, for example, the control center, can and should appear as the main organ providing the commander with firm and constant management of the combat activity of troops. At the front this organ will be the operational control center; in the army -- the tactical-operational control center, and in the division (corps) - the tactical control center.

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In our opinion, the control center has to be created to fulfill the basic function of providing constant control of the troops -- an operational function -- under the direct leadership of the chief of staff and to actually be the forward command post.

The operational control center (at the front) has to be composed of: the commander of front troops, a member of the Military Council, the chief of staff, the operational directorate of the staff, operational units from the apparatus of the chief of intelligence, of the chief of missile troops and artillery, of the chief of PVO troops, and in some cases operational groups from the staff of the air army of the front and the navy (VMF); also the minimum number of personnel necessary to provide support, servicing, and protection.

The nucleus of the operational control center is made up of the operational unit of the staff of the front with the chief of staff at its head; its basic working apparatus is the operational and intelligence directorates. Besides, in all operational matters the apparatus of the chief of missile troops and artillery, the apparatus of the chief of PVO and the operational groups of the staff of the front air army and VMF, are subordinate to the chief of staff, as the first deputy to the commander of troops. The chief of operational control has to direct all practical, everyday, executive aspects of the work of the operational center, of control and supervision over its quality and timeliness.

The make-up of the operational control center, the principle of its work, and coordination with the system of various control points are shown on Diagram #1.

The immediate work of the operational control center (at the front) is carried out, in our opinion, on a so-called operational plotting board, understood to mean a unified work area of the command, officers, and generals -- who represent the various departments, directorates, and operational groups. Maps (plotting boards), that continually show the situation in an easy-to-follow manner, are located at this work area.

[redacted]

1.3(a)(4).

[redacted]

1.3(a)(4).

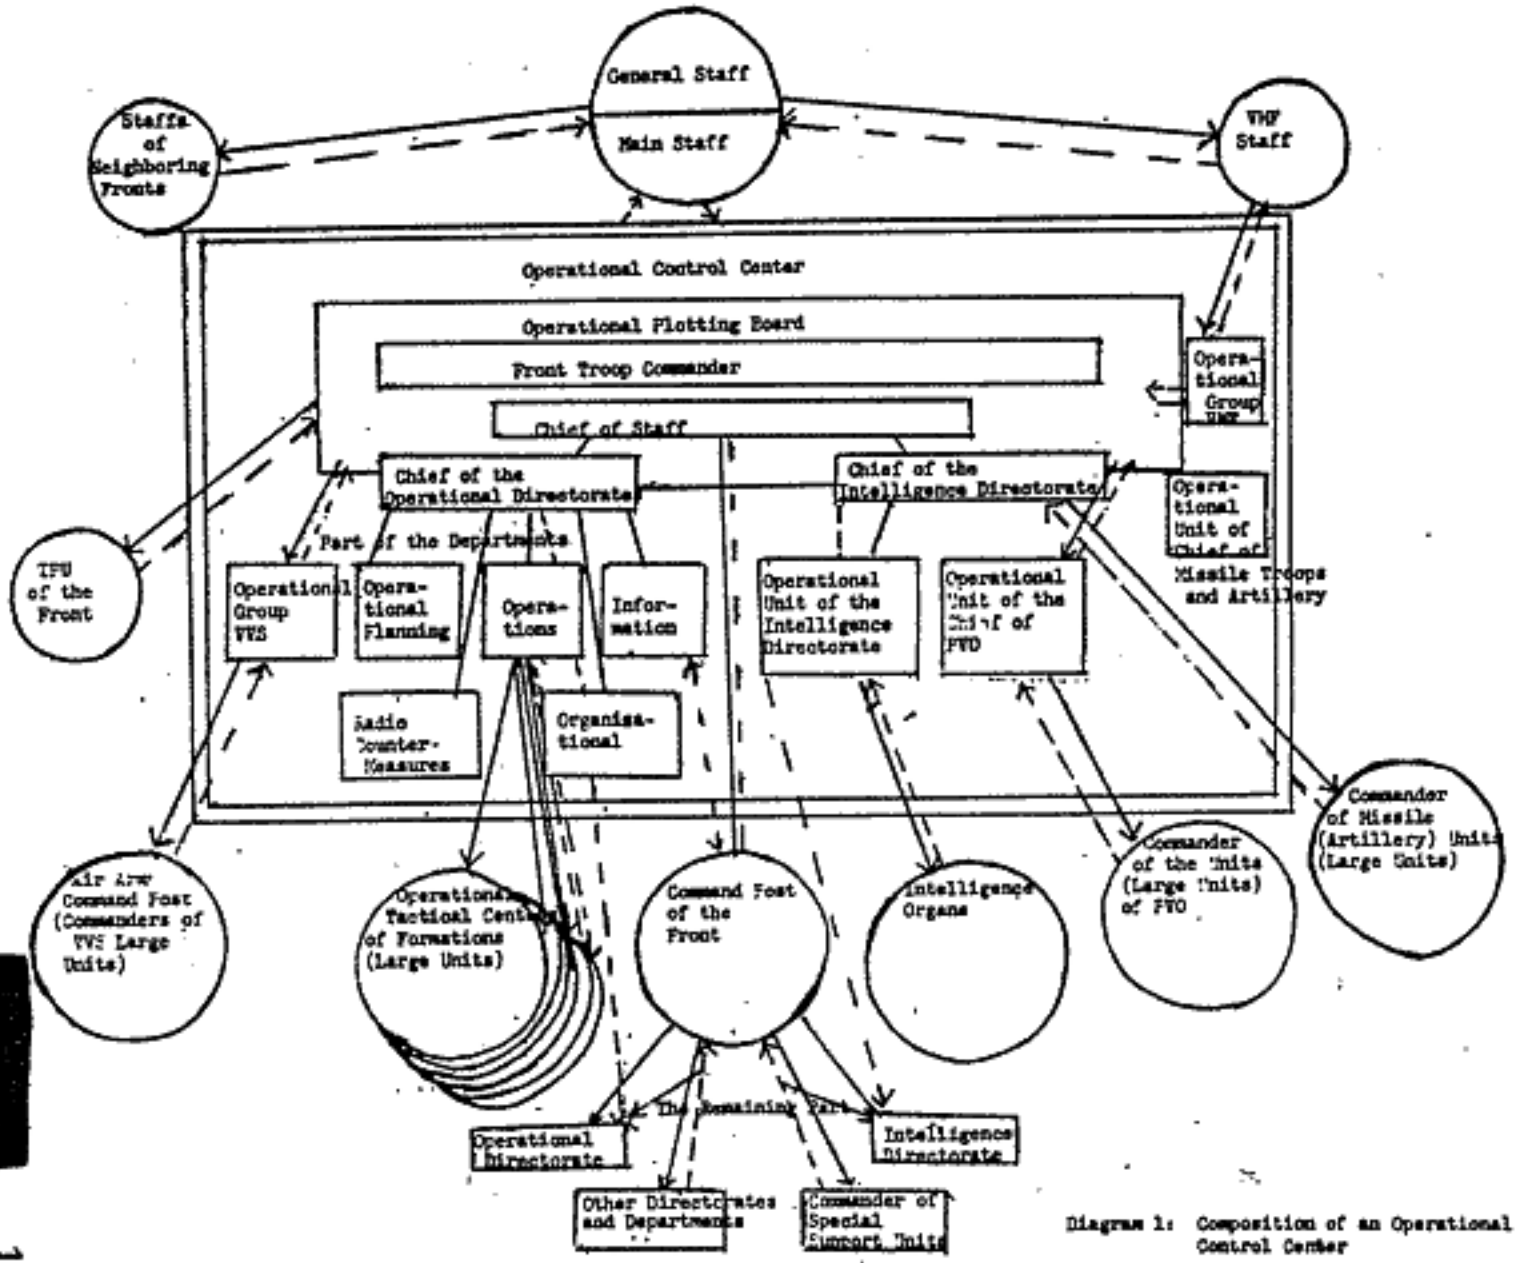

Diagram 1: Composition of an Operational Control Center

1.3(a)(4)

1.3(a)(4)

1.3(a)(4)

In the main, the organization of the work of the operational control center on the operational plotting board appears to be as follows:

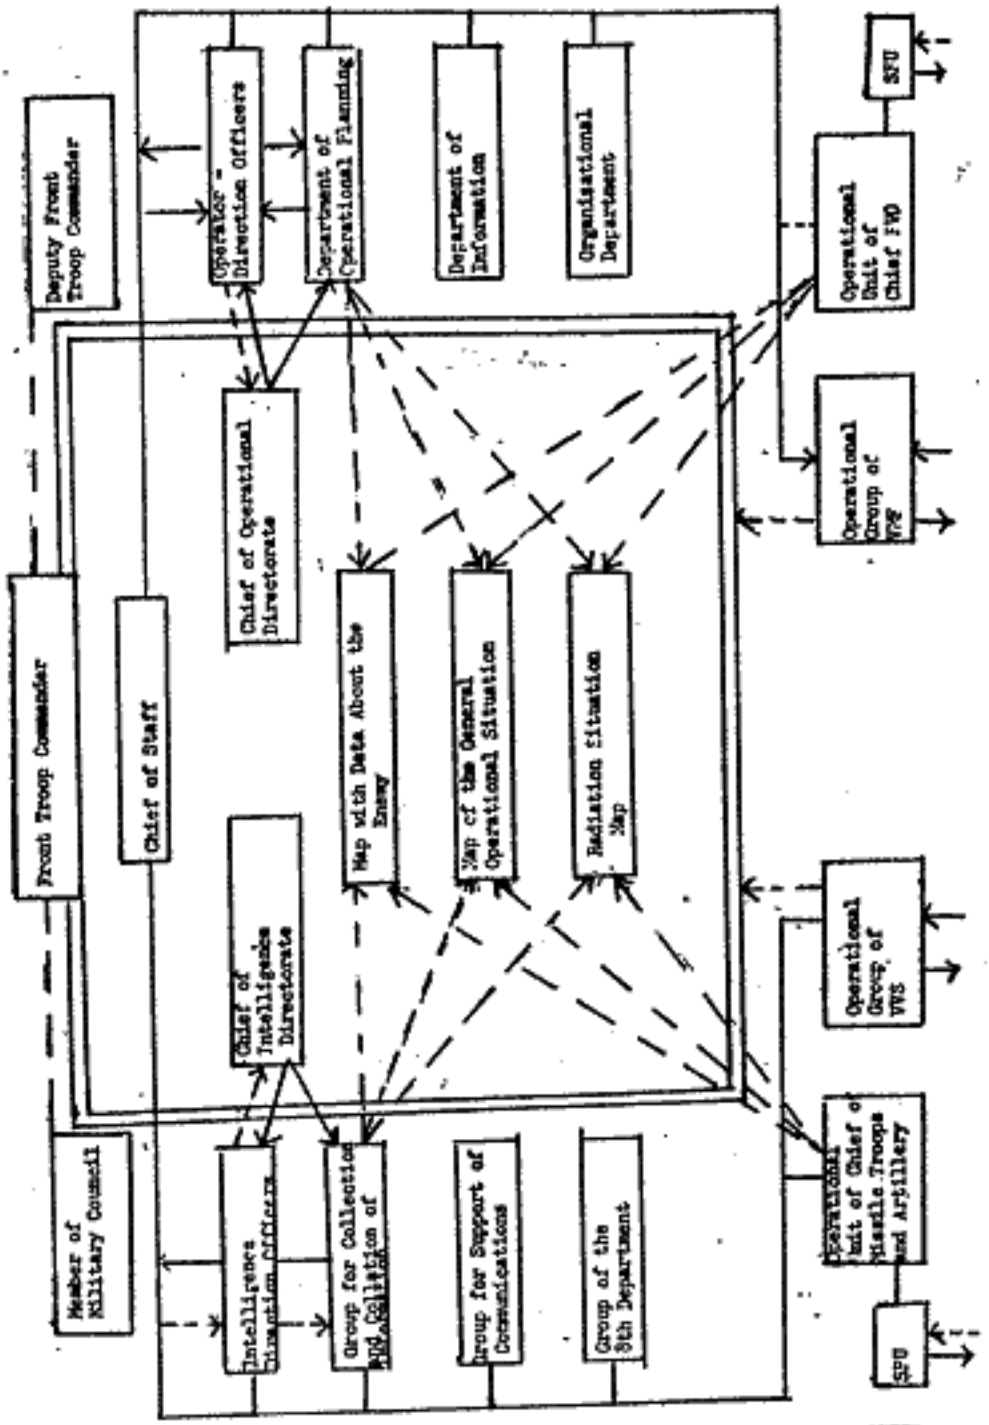

Diagram 2: Organization of the Work of An Operational Control Center

[redacted]

1.3(a)(4)

As shown on Diagram #2 all situation information goes to the operational plotting board of the control center. Its location is the basic work area of the front troop commander, the chief of staff, the chief of the operational directorate, the chief of intelligence, and, when necessary, the chiefs of the arms of troops and chiefs of the operational groups of the staff of the front air army and VMF.

The operational plotting board is operated by the operational planning department of the operational directorate. The chief of the operational directorate and the chief of the department of operational planning are responsible for continuous operation of the operational plotting board. In our opinion, all the work is done on three maps: the map with information about the enemy, the general operational-situation map and the radiation situation map. Access of persons to the operational plotting board should be strictly limited.

It would be best to use a light prefabricated building to house the operational plotting board, where all the above-mentioned persons could work together and where there would be facilities to allow for concurrent work of the duty shift of plotting board operators. Specially adapted staff busses, and in individual cases even army supply directorate (USB) and standard medical (UST) tents, can be used for this purpose when necessary.

The special control points (operational units) of the chief of missile troops and artillery, the chief of PVO, and the operational groups of the staff of the front air army and the VMF, and also other departments and groups included in the composition of the operational control center, are located close to the place where the operational plotting board is housed.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4).

[redacted] 1.3(a)(4)

The remaining personnel of the field command, who are not part of the operational control center, will become part of the command post or rear area control point (TPU), in accordance with the functions they fulfill. The interlocking of all three elements of the field command -- control center (the forward command post), the command post, and the rear area control point -- must fulfill the needs for a concealed and dispersed deployment in the terrain, and should be provided with reliable internal communications that would permit the carrying on of conversations in the clear.

The organizational structure of the control centers that we propose gives us the opportunity to relieve the front troop commander (army commander and division commander) of the great loss of time needed to hear the situation reports, and will give him the opportunity to allot more attention to situation analysis and execute purposeful direction of troop combat activities.

The organization of such a control center also gives us the opportunity to eliminate the separation of collection, processing, and reporting of situation data about friendly troops, about the enemy, and especially about the radiation situation, which is very important under modern conditions. All information will be concentrated in one place and is reported directly to the commander.

At the command post there has to be a reserve operational plotting board with a group of plotting board operators, that would duplicate the plotting of the entire situation, in order to provide for the control of troops when the control center (PKP) is moved or in the event it is put out of action, to assume the control of troops.

On an analogous rear area operational plotting board must be entered all the rear area situation data, that is essential to making decisions concerning uninterrupted materiel-technical and medical support. The plotting of the missile rear area situation has to be done with extreme attention to operational use.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In our opinion, a necessary condition for stability of work at the control center has to be good technical equipment, especially with regard to means of communications and specially adapted staff transport. First of all, we have in mind, the need to organize and maintain dependable communications with all sources (shown on Diagram #1), providing situation data to the operational center. In this, special attention has to be given to the creation of separate communications channels for the command, for chiefs of troop directions (napravleniye), for the chief of missile troops and artillery (only in the channel to subordinate units and large units), the chief of PVO (in the channel of PVO troops), the chief of intelligence, and also special communications links with the general staff, with coordinating large units (formations) and with the staff of the front air army.

Just as important is the internal voice communications net, and also the television equipment which would ensure a free exchange of conversations within, as well as between, every control organ. Besides, a number of monitors (korrespondent) (who are relied on for this) must have the opportunity to determine that conversations on the internal system are in progress, by means of a special indicator (tablo), and when necessary to monitor the conversation in parallel or participate in it.

An important consideration is the need to transmit all reports to the operational plotting board, or the orders (commands) from the operational plotting board, via the internal voice system, to the chiefs of directions or to control points of the chiefs of the arms of troops, by clear text. In turn, they both, in communicating with the troops, must receive and transmit by means of encoding devices or cryptographic security (SUV) documents.

Such control centers already exist at the command posts of large units of PVO of the Country and in the staffs of fleets, and they fully justify their existence. It seems to us that there is a direct need to test, during exercises, a similar system of control in the ground troops.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Considering our special interest in fulfillment of staff operational functions, we consider that operational control, as the basic function of the apparatus of command and of the staff also has to undergo changes in its organization, that would fully reflect the nature of the work they perform.

It is expedient to have the operational control of the front staff composed as follows: chief of operational control and his deputy, the departments of operational planning, operations (12 to 14 persons, basically direction officers), information (6 persons), radio countermeasures (4 persons), and organization (10 to 12 persons).

The operational planning department, composed of 10 to 12 persons (6 to 8 operations officers, one chemical, one engineer, 1 or 2 nuclear weapons specialists) prepares suggestions for making decisions regarding the use of front troops in an operation, and prepares the decisions of the front troop commander, in graphic or written form. During the course of combat operations, the officers of this department plot all the operational situation data on the operational plotting board /4 or 5 words missing/ reports to the command. They also maintain the radiation situation map, without which it is difficult to determine the degree of safety of friendly troops while they execute any maneuver on the battlefield, and take into account the average doses of radioactivity received by units and large units. The indicated composition of the department can ensure work at the control center in two shifts.

Practice shows that the operational directorate has to solve many organizational problems in addition to the operational ones, and has to utilize the working staff of the basic departments for this. This practice does not justify itself. It seems to us that it is necessary to include a reconnoitering group (2 or 3 persons) in the newly organized organization department, for carrying out reconnoitering of control point areas

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

and the placement and relocation of the latter. It should be assigned the duty for the area where the control points, units and subunits of support, servicing, and protection and also the organization of chemical and radiation detection are located; for this purpose it would be expedient to give the group a special observation post. Moreover, the organization department must have an administrative support group (2 or 3 persons) in charge of matters dealing with the organization of food and administrative outfitting of control points, and a group to perform classified work (5 or 6 persons), serving the whole staff of the control center.

The total staff of the operational directorate will be about 50 to 55 officers, enlisted men, and employees.

The diagram of control centers and other views on various questions of troop control, and the organizational structure of the control organs that we propose, are not necessarily without fault. It would be desirable to have other opinions expressed on the respective questions, which will help to solve them correctly.

Major-General A. Morozov

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

* * *

Planning the use of nuclear weapons in a front offensive operation is the principal question in modern conditions, but it is solved by applying the old methods of planning to the new conditions.

Experience gained from the exercises carried out in the Turkestan Military District brought us to the following conclusion. As a result of the fact that, at the front, nuclear warheads and means of delivering them to the target are found under the subordination of various chiefs (the air army commander and the chief of missile troops and artillery), a lot of time is wasted by the troop commander when making the decision to use these weapons in an operation for the coordination of the questions: with which weapons by whom, where and when must the strike be made. Normally, upon receipt of the operational directive, the chief of staff of the front informed the commanders of arms of troops and the chiefs of directorates and services about the combat mission received and announced the preliminary decision of the front troop commander. After this the plans for using nuclear weapons were prepared simultaneously in the operational directorate, by the chief of missile troops and artillery and in the staff of the air army. Later these plans were coordinated by the chief of staff of the front; in order to do this he listened to the views of the appropriate commanders, which consumed a lot of time. As a result of the limited time, the problems of planning the use of nuclear weapons, recording the rate of use of nuclear weapons, and the radiation situation, its analysis did not achieve the requisite solution.

A conviction arose, as a result of analysis, that the need had arisen for a special organ attached to the troop commander and the chief of staff of the front, for planning the use of modern means of combat, because the content of the questions solved by the staff of the front and the amount of work do not correspond to the existing organizational structure and had exceeded its limits.

When preparing for the front commander-staff exercise that was carried out in April 1960, a special group was created under the operational command of the staff of the front to plan the use of nuclear weapons and was composed of seven persons. The group was headed by the deputy

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

chief of the operational directorate. It was composed of the senior officers of the operational directorate, the staff of the chief of missile troops and artillery, the air army staff, the chief of chemical troops, the engineer troops staff, and the front staff intelligence directorate.

The group was assigned the following four basic tasks: preparation of considerations concerning the use of nuclear weapons for the front command, control and recording of the receipt and rate of use of nuclear weapons, recording of the radiation situation, and organization of troop antinuclear protection. Before the start of the exercise the volume and procedure of the work of the group and the functional duties of each officer were delineated. The chief of the group had to prepare and report to the chief of staff, or to the front troop commander, proposals for the most expedient use of nuclear weapons, and during an operation to summarize, analyze, and report all information regarding the use of nuclear weapons by both sides, and in particular, the radiation situation in the areas of combat operations and in the rear area of friendly troops.

It was decided that during the exercise the group would be located at the front command post since, basically, troops are controlled from there. However, experience showed that under the conditions of the Middle-Eastern (sredne-vostochnyy) Theater of Military Operations, when the commander often leaves the command post during the operation, and directs the troops from the forward command post, a group of this type has to be located with the front commander at the forward command post. One staff bus was allocated for the transportation and work of the group.

In the future, in our opinion, with the creation of such a group (department) it is necessary to take into consideration its ability to divide into two parts which have equal capacity for work, so that in case one part is put out of action the other can continue to fulfil the assigned mission.

When, during the exercise, the directives of the Supreme High Command for an offensive operation were

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

received, the group began its basic work of planning the use of nuclear weapons. Based on the operational orientation given by the chief of staff of the front, which was attended by the group chief, the group was given its primary assignment -- to plan in detail the use of nuclear weapons in the first strike and during the fulfillment of the immediate and follow-up missions by the front troops.

First of all it was determined that the front would have 48 units of nuclear ammunition available for the start of the operation, ready for use, including 34 missiles, 6 front cruise missiles (krylataya raketa), and 8 atomic bombs. During a thorough analysis of the situation it was determined that it was possible to use only 36 of the 48 units for the first strike, because of the 18 troop missiles, 12 missiles were located in divisions deployed far from the State border, and their use in the operation would be possible only after these divisions were committed to combat. Then enemy targets were evaluated and it was determined that it would be necessary to neutralize and destroy 29 targets with the first strike. However, using its own facilities the front could only carry out a strike against 20 targets and use 25 units of nuclear ammunition. The remaining 9 targets were located far in the rear, and strikes against them could be made more expediently by the means of the Supreme High Command.

After identifying the targets, the coordinates of the epicenter of the explosion, the numbers, yields, types of warheads and the nature of the burst, a chart was drawn up, showing the nuclear strikes to be carried out, with tentative determination of the results expected from the strikes.

In this way the group determined in detail the targets and the number of nuclear warheads for each target in the first strike for fulfilling the immediate and follow-up missions, and also those held in reserve by the front troop commander. All this work was coordinated with the chief of missile troops and artillery and the air army

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

commander. The front chief of staff and the front troop commander were forwarded the proposal for the use of nuclear warheads, which became the basic plan for the use of nuclear weapons.

A separate plan for the use of nuclear weapons was not prepared; everything was represented graphically on the plan of the operation, including the targets of the strikes, the yield of the charge, the type of burst, the time of the strikes, and alternate targets were also shown there. The ratio of forces in regard to warheads and means of delivery, and the distribution of nuclear weapons by missions were set out in tables on the map. Unified signals were established to carry out the nuclear strikes and were brought to the attention of the missile units and aviation. Combat orders for antinuclear protection of troops and installations were developed and were coordinated with the chief of chemical troops, chief of the rear, and the staff of the air army. During the planning period of the operation, the group prepared a map showing all the targets slated for neutralization and destruction by nuclear weapons, and the location of friendly troops and rear area installations; later nuclear strikes of both sides and the radiation situation were entered on the map. In this way the first stage of the group's work in planning the use of nuclear weapons ended.

During the combat operations, the group was busy identifying enemy targets, and when the troop commander made the decision, they planned the strikes against them, took into consideration the receipt and rate of use of nuclear weapons, and also kept track of the radiation situation, especially in cases of surface bursts. The results of the enemy strikes were analyzed and conclusions were drawn concerning the radiation situation and the possibilities for friendly troops to operate. Through the staff of the chief of missile troops and artillery and the air army staff the group kept track of the delivery of nuclear strikes and plotted them on the map; the dispositions of the troops were also plotted on the same map.

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4)

The group received information about the enemy through an intelligence officer of the intelligence directorate, from troop reports, and from air army staff reports. Based on this information, targets that had to be destroyed or neutralized by nuclear means were identified and evaluated. Conclusions were reported to the chief of the operational directorate and, more often, to the chief of staff of the front, after which the troop commander made a decision and assigned the mission of carrying out the strike directly to the chief of missile troops and artillery or to the commander of the air army by word of mouth or in writing; in the latter case the orders were prepared by the group.

While working out the proposals to use nuclear weapons the group was in constant contact with the directorate of artillery armament, the air army staff and the front rear area staff, and was informed about the receipt and readiness of nuclear weapons and the provision of the missiles with special fuel. An officer from the chief of missile troops and artillery supervised the deployment of combat formations of missile units and officer-pilot supervised the basing of delivery aircraft; all this information was also plotted on the map.

During the exercise the group tried to keep track of losses inflicted on friendly troops by enemy strikes, but did not fulfill this task because it did not get the necessary summarized data from the troops. They came to the conclusion that the groups can give the losses only for separate strikes and for individual large units, and that the organizational and operations directorates should have the information about general losses as a result of nuclear weapons as well as from other means of destruction.

During the exercise the special group did not have selector communications (selektornaya svyaz) with the other directorates of the front staff. This should be considered to be an abnormal situation. Experience gained from the exercise showed that the group must have

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4).

[redacted]

1.3(a)(4)

such communications with the intelligence directorate, the combined command post of aviation and PVO, and also with the troop commander and chief of the front in order that all the information about the enemy that reaches the intelligence directorate and the combined command post be transmitted immediately to the special group and be quickly plotted on the map and reported to the chief of staff and the commander.

As shown by the experience gained from the exercise, it is essential to have a map-screen (karta-ekran) on which all the enemy targets slated for neutralization or destruction are plotted. This will greatly simplify the work of the front troop commander in making a decision about the carrying out of nuclear strikes.

It should be considered a fault that officers -- representatives of staffs and directorates -- were not part of the operations directorate and were constantly overloaded with work in their staffs and directorates which reflected negatively on the work of the group.

Because such a group was organized for the first time in a district, many questions had to be resolved by feel, but during the exercise it played a big role and rendered considerable help to the front command in the timely and purposeful planning of the use of nuclear weapons. In many ways it simplified the work of coordinating strikes between aviation and missile units. At the critique of the exercise, the district troop commander pointed out that the group performed a large, useful task and that in the future it is necessary to create similar groups.

The group was created under the operations directorate of the front staff, but during the exercise it worked under the direct management of the front chief of staff and front troop commander and provided them with information, because in the final analysis, the decision to use nuclear means is made only by the troop commander. In addition /one line missing/ did not fulfill the missions assigned to it.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

In connection with this, the conclusion arises that there should be a similar permanent element directly subordinate to the chief of staff of the front who would work in close contact with the operations directorate. The staff of such a planning organ must be part of the T/O and be prepared in advance.

In our opinion it is necessary even during peacetime to have in the staff of the military district and directly subordinate to the district chief of staff a special department of modern means of combat and troop protection from weapons of mass destruction subordinate directly to the district chief of staff. In peacetime this department has to train the lower staffs in matters of planning the use of nuclear means, develop measures for and manage the protection of the troops from the means of mass destruction. In wartime such a department has to be expanded into a special directorate headed by the deputy chief of staff of the front. It should concern itself with planning the use of new means of combat and measures for protecting troops from weapons of mass destruction.

Lt. General N. Lyashchenko

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

* * *

We consider it necessary to enumerate a series of suggestions for the improvement of organizational structure of modern staffs, their equipping, and methods of work.

The existing organs of control, as was already mentioned in our press, do not fully conform to modern conditions; they are too cumbersome, have little mobility and their means of movement do not have adequate cross-country ability over the terrain. It is enough to point out that the staff and command of the army have up to 1,500 persons in their composition and up to 350 various motor vehicles, the staff and directorate of a division -- up to 500 persons and more than 100 various motor vehicles. These staffs are tied to the roads and bridges; it is difficult to move them; a lot of time is required for their deployment and redeployment, especially of army staffs. When, during offensive operations, tanks and motorized-rifle divisions move at a speed of 80-110 km per day, the staffs lag behind the troops.

It is also known that under conditions of mass use of nuclear/missile weapons the commander's decision has to be made, relayed to the executors, and carried out in a very short period of time, in many cases calculated in minutes or even seconds. Great command mobility is necessary for the successful control of nuclear/missile weapons. It is possible to have missiles with nuclear charges, tank, and airborne troops and not attain success because of tardiness in the combat use of these means.

It is necessary to review the organization structure of the staffs and sharply reduce the number of personnel and the means of transport in them. Success in the control of troops during modern operations will depend not on the number of generals and officers in the staff, but on the quality of their training, experience, the coordination and operational efficiency of the work, and also on the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

technical equipment of the staffs. The control methods, by small operational groups, used in the tank troops during World War II, can be wholly and fully utilized even under modern conditions. The staffs and directorates of these large units and formations moved up in tanks or motor vehicles with radio sets, were noted for their high mobility and were trained and adapted for troop control in mobile types of combat operations.

In our opinion, instead of an army staff and staffs of the commanders of arms of trooops and services, it is necessary to have a single staff for field command of an army with the chief of staff of the field command as head; at the same time he would also be the first deputy army commander. Organizationally the army field command must contain:

- the army command;

- chief of staff of the field command;

- department of operational and combat management of troops in operations and in battle;

- chiefs of arms of troops and services and their departments;

- the Party-political apparatus;

- army deputy commander for the rear area and control organs for the rear area.

The staff of the army field command must have the necessary combat and technical equipment supply units and subunits subordinate to it.

In our opinion, the army field command, from the operational-tactical standpoint must be divided into a forward command post (PKP) and a rear command post (TKP).

The PKP can be composed approximately as follows:

- army commander;

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

- member of the Military Council;

- chief of staff of the army field command;

- a group of officers from the operations, intelligence, and communications departments;

- chief of missile troops and artillery with a group of officers;

- chief of engineer troops with a group of officers;

- chief of chemical troops with a group of officers;

- chief of the PVO with a group of officers;

- deputy commander of the rear area with a group of officers;

- a group of officers, sergeants, and soldiers for combat security and guard duty.

In our opinion the PKP of the army must have altogether 45 to 50 generals and officers, 70 to 75 soldiers and sergeants, six tanks (three T-54 and three PT-76), 15 armored personnel carriers BTR-50P, 10 airplanes or helicopters, and also the necessary means of communications, radio sets, radar sets and television sets mounted in tanks, armored personnel carriers, helicopters, and airplanes.

The army rear command post will ensure, on orders from the army commander, the supply of technical equipment to the troops and, at the same time, will be the reserve control point in case the PKP of the army is put out of commission. It is headed by one of the army deputy commanders and can be composed approximately as follows:

- deputy army commander;

- deputy chief of the army political department;

- first deputy chief of the army field command staff;

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4)

- deputy chief of the rear /one or two words missing/;

- a group of officers from the operations, intelligence, chemical, engineering, political, PVO, and communications departments, and the department of the chief of missile troops and artillery;

- rear area officers, specialists in artillery, tank armament, motor vehicles and tractors, quartermaster, and fuel and lubricant (GSM) supply.

Directly subordinate to the army rear area command post will be:

- reserve commands for divisions and regiments;

- troop units and subunits for the elimination of the effects of enemy nuclear attacks and antinuclear and antichemical protection;

- depots and portable repair plants.

The advantage of this organizational structure of the army field command is, in our opinion, that all departments of the presently existing staff, and also the chiefs of arms of troops and services, will be directly subordinate to the chief of staff of the field command, since he is the first deputy commander. This will make it possible to concentrate all planning of an operation (battle) and the control over all forces and weapons in an operation and in a battle, in the hands of one person.

In the division command there should be, in our opinion, 12 to 15 generals and officers, among them a divisional commander, chief of staff of the division command, chiefs of arms of troops and services, and the Party-political apparatus. Analogously we propose that the army unit sub-divide the division command into a forward command post (PKP) and a rear command post (TKP).

The division PKP should have 5 medium tanks, 3 PT-76 light tanks, 3 armored personnel carriers and an air

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4)

flight (zveno) (3 to 5 MI-1 or MI-4 helicopters).

The creation of PKP and TKP as part of the army field command and division command increases, in our opinion, the combat readiness of the staffs, the mobility of command posts and their viability.

The existing cumbersome staffs reveal themselves by the presence of a large number of antennas, radar sets, busses and motor vehicles with high bodies. Besides, these vehicles are easily shot up with automatic weapon fire, and are pierced by mine and shell fragments. Under these circumstances it is difficult to camouflage the staffs and reliably ensure their viability. During combat operations in separate directions, in the presence of gaps and breaks in combat formations, with a sizeable separation of individual units and large units from the main forces, the staffs can be destroyed not only by nuclear weapons and aircraft, but also are subject to tank and infantry attacks, including enemy diversionary groups.

For this very reason the control points which we propose should be in tanks (T-54, PT-76), armored personnel carriers, and armored staff cars, as a result of which they will have cross-country ability to go anywhere, maneuverability, be small in number, have high viability, and will not stand out from the other tank and armored personnel carrier subunits. The presence of airplanes and helicopters in the control points will make them even more mobile and maneuverable.

In line with the change in the organization of the staffs, it is necessary to review the methods of planning operations and combat actions, and also the manner of troop management during the operation. In our opinion the plan of combat and operation under conditions of a nuclear/missile war has to consist of short combat documents. The absence of lengthy operational pauses, during which the planning and preparation for approaching operations was previously carried out, will probably make it necessary to carry out all planning during combat operations. Under these conditions there will not be time to prepare voluminous documents.

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4).

[redacted] 1.3(a)(4)

In our opinion the plan for an operation and battle has to indicate the goal of the operation (battle), which enemy grouping will be destroyed by nuclear weapons, which targets or territories are to be taken by combined-arms large units and units, the depth of the mission, the direction of the actions (mainly of the airborne and tank troops), the time for fulfilling the mission, and also the questions of supply of material-technical equipment and control of the troops. All this should be noted on maps.

As soon as we abandon bulky operational plans and other operational documents, and superfluous military bureaucracy, cumbersome staffs will not be needed and there will be more operations and real management of the troops.

Everyone knows that the generals and officers of modern staffs and directorates of armies and divisions waste two-thirds of their time processing various types of documents that often are not needed for their work, and only one-third of their time is used for the direct control of troops, which is also done by only a small group, and not by the overwhelming number of staff generals and officers. To abolish decisively the unnecessary paperwork that has increased 2 or 3 times during the postwar period means the release of a large number of officers for specific control of troops in combat and operations. It would be more useful to employ the released generals and officers for the creation of reserve PKP and TKP which can be used in case the basic control points are put out of commission.

The organizational structure of large units, and units exerts great influence on the firm control of troops.

In our opinion the modern organization of an army, motorized-rifle division, and tank division do not conform to the conditions of modern missile/nuclear war. They are cumbersome, have little mobility, inadequate maneuverability and are difficult to control during combat and battle. This organization has had its day and has become obsolete, the same as the organization of modern staffs.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Without going into detail, we propose to switch to the brigade principle of structure for the combined-arms formations. Modern ground troops, it seems to us, have to be composed of missile divisions and brigades, of tank, mechanized, and airborne brigades.

The army (possibly, it is better to call it the mobile combat group - BPG) is not constant in its composition. Its composition depends on the combat task to be fulfilled, the depth and width of the offensive zone, nuclear weapon support, and other conditions.

In the makeup of the army (BPG) it is necessary to have about: 5 to 7 tank or mechanized brigades (in any ratio), a missile brigade, two airborne brigades, 1 or 2 engineer brigades, 1 or 2 chemical troop brigades, 3 to 5 medical battalions (detachments), a rear services brigade, and a reserve brigade. For combat security the army (BPG) has to have an aerial reconnaissance regiment, an armored reconnaissance regiment, reconnaissance /6 to 8 words missing/. Besides, it may receive 1 or 2 missile brigades, an air division of fighter-bombers, a river-crossing brigade, and a chemical protection brigade as reinforcements.

The tank brigade must consist of from 3 to 5 tank battalions, and a battalion of organic missiles (voyskovaya raketa). A brigade may have up to 100 tanks, 50 percent of them light; in a mechanized brigade - correspondingly 3 to 5 mechanized battalions, 1 or 2 tank battalions, and a battalion of organic missiles.

All army rear services elements should be combined into a rear services brigade, and the rear services of tank (mechanized) brigades -- into a rear services battalion. The rear services have to be deployed on tracked or other vehicles with high cross-country ability. Helicopters have to play the principal role in the supply of nuclear weapons, for which the army has to have a regiment of helicopters (30 units), and about 10 helicopters in a brigade.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Tank and mechanized brigades have to receive clear and specific tasks in great depth in order to achieve the final goal of the operation.

Notifying troops of their tasks has to be done by short combat orders through technical means of communication, by personal contact, or by delivery to battalions or brigades by airplane, helicopter, or tanks,of situation maps with the assigned mission.

It seems to us that the methods of control of troops stated above will provide the opportunity to plan a battle and operation in a more efficacious manner, and control the troops in a more concrete manner during them.

Only a few general problems regarding organization of control in modern operations are stated here. They can be resolved in greater detail and checked out only during command-staff and troop exercises. For this reason it would be expedient to carry out a series of exercises for the purpose of detailed study and development of problems of troop control, since the methods of troop control that now exist are in need of fundamental review.

The Deployment and Forward Movement of a Combined-Arms Army of a Border Military District in the Initial Period of a War

Lieutenant-General S. Andryushchenko

In the event of the sudden unleashing of a war by the aggressive imperialistic states, and the absence of a threat period, (ugrozhayemyy period) the combined-arms armies of border military districts may find themselves in a difficult situation. The territory on which the troops of an army are dispersed may be subject to enemy nuclear/missile strikes of various yields, to chemical/missile strikes, and also to the use of bacteriological agents.

We have set the goal of studying theoretically insofar as possible, all aspects of the conditions of deployment and forward movement of a combined-arms army in the area of combat operations, and to check out some of the problems in practical troop and command-staff exercises. In addition, we studied the combined-arms army made up of four or five divisions (two or three of them up to strength and the rest in cadre form, or at reduced strength) with a minimum amount of frontal means of reinforcement. The composition of the enemy was taken to correspond with his actual formation, and the probable methods of conducting combat operations in concrete operational directions were taken into consideration.

In the conditions resulting from a sudden attack by the enemy, the nature and scope of the work of field control of an army and of commanding officers and staffs of large units (units) will seem unique. The basic measures of the commander and the staff of an army in this period should be as follows:

- to evaluate thoroughly and in the quickest possible time the apparently serious and complex radiation, chemical, and bacteriological situation evolving in the entire area of army deployment; determine the degree of disruption of control and communications, the condition of the troops, their combat effectiveness, security, and losses, the condition of materiel reserves, and communications routes;

- to clarify, without delay, the decision which was made earlier to move the troops forward from their permanent disposition points into areas of concentration, taking into consideration the possibility that these areas are contaminated; to determine, in compliance with the operational assignment of the army, tentatively, the problems of

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

constant combat readiness in future operations of large units and units, to utilize all means and methods for the most expeditious method of notifying the troops of the decision;

- to restore the disrupted control of and communications with the large units, units, and senior commander (nachalnik);

- to reestablish disrupted control and communications with the large units, units, and the senior commander;

- to take measures to eliminate the results of an attack by weapons of mass destruction;

- to organize evacuation, dispersal, and replenishment of materiel supplies;

- to determine the order of entrance on duty and processing of those reservists, draftees, and technicians arriving to join large units in cadre form or at decreased strength, taking into consideration the fact that the terrain in the conscription areas and the routes of movement may be strongly contaminated by radioactive or poisonous chemical substances and by bacteriological agents;

- upon receiving the operational directives from the district headquarters, to clarify and execute the plan worked out previously to commit the army troops in the area of combat operations, or, in the case of an abrupt change of circumstances, to work out a plan for regrouping the troops in a new direction; take measures to conclude quickly the preparation of large units and units for a prolonged march, the reconnoitering of the routes of forward movement, reconstruct sections of roads and road structures that were destroyed, organize the commandant's service, combat security, and material-technical support; order full mobilization of the large units and units designated for the formation of secondary echelons in a limited amount of time, or alter the mobilization plans; make a decision regarding the subsequent forward movement of the mobilized large units and units directly behind the troops of the first echelon;

- maintain constant control of the troops.

All the above-listed measures must be carried out simultaneously, within a short period of time, measured in hours, and even in minutes, apparently under circumstances during which considerable losses may have taken place in command complements.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Upon completion of the first of the indicated measures - evaluation of the radioactive, chemical, and bacteriological situation - we immediately come up against a series of difficulties; it is impossible to overcome these difficulties with the forces and equipment at the disposal of the army, and even of the front. In case the opponent uses weapons of mass destruction first, it is of primary importance to evaluate the situation not only in the areas subjected to the strikes, but to foresee with sufficient clarity the possible contamination of the entire disposition area of the army troops, due to the spread of radioactive and poisonous substances in the direction of the wind. In order to arrive at a practical decision regarding the regrouping and subsequent troop operations, the army commander must quickly receive precise data regarding the number of enemy nuclear strikes, the coordinates of their centers (ground zero), the type and yield of the explosion, and the direction and velocity of the wind at various altitudes in the area of army troop disposition, and in the adjacent areas. Without this data it is impossible to evaluate the radiation situation, even by the analytical-computer method (raschetno-analiticheskiy metod). The instruments for detection of radiation and chemical contamination which are available to the troops are not capable of forecasting radioactive fallout by tracking the various radioactive clouds, and do not permit the determination of a drop in the level of radiation in the contaminated areas. This is a very important problem, as well as one that is very difficult to solve under present conditions.

As we see it, its solution must be realized on a nation-wide scale if we consider that the above-mentioned data will be essential not only for the ground troops, and the armed forces as a whole, but also for enterprises of the national economy and the civilian population.

Apparently it is necessary to set up automatic intersection points (avtomaticheskiye punkty zasechki) for locating nuclear bursts, capable of determining the parameter of the burst, and determine all, or most of the above-mentioned data. These points should be united by analytical-computer centers, where the incoming data are processed, collated, and relayed to the analytical-computer groups of formations, large units, and the command points of PVO of the Country and of civil defense.

In our opinion it is necessary to create analytical-computer groups in the army and in the military district in peacetime, primarily to process and transmit to the troops the data coming in from the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

analytical-computer centers, and also to determine drops in the levels of radiation after certain periods of time, and transmitting them to the troops. In addition, during forward movement and front and army troop operations in enemy territory, they will naturally need their own organic analytical-computer groups, capable of quick and accurate forecasting, and determination of, the radiation situation, at least within the boundaries of the offensive zone of the front and the army, and the nearest adjacent territory. These very groups, in the event that they are relieved, or leave the specific area, have to transmit in written form (dokumentalno) the latest data about all sectors contaminated by radioactivity to the other large units (units), in the same way as all information on mine-fields was transmitted on a form (formulyar) during the last war. The make-up and equipment of the analytical-computer groups still require some thought. However, it is already quite clear that they must have the most modern detection instruments (pribory razvedki) and special machines for reproducing radiation situation maps for the troops. In our opinion, these groups, which consist of operations officers (ofitser operator), chemists, intelligence officers (razvedchik), and topographers, should be headed by the chief of the chemical troops of the front and the army.

The creation of automatic intersection points for locating nuclear bursts and the analytic-computer centers will apparently fall, of necessity, to the system of PVO of the Country, inasmuch as it embraces the entire territory of the country, and the additional introduction of the indicated points and centers will require only a partial improvement on its part. Corresponding analytic-computer groups should be formed under the operational formations. We are convinced that carelessness in the setting of these posts and centers can lead to excessive human losses.

In addition to evaluating the situation in terms of radiation and chemical contamination, it is also necessary to evaluate the bacteriological aspect. The army has no such capability. It is known that almost all bacterial agents have an incubation period from a few hours to tens of days. In this light the great danger that the troops will be subjected to becomes quite evident if the contaminated areas are not identified immediately and excluded from occupation by large units and units. This problem, in our opinion, should also be resolved on a nation wide scale, by creating special antiepidemic detachments under hospitals, clinics, and medical establishments, by bringing in civilian medical cadres and the local population. The personnel must (4 or 5 words missing) training, and the detachments should be supplied with instruments, equipment,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

and transportation.

It is equally important to secure from destruction, primarily by radiation and poisonous substances, the personnel and equipment which is being mobilized and is arriving from the national economy, especially from industrial centers which have been subjected to strikes. It would seem that the ideal situation would be one where the personnel and equipment are directed to the reception centers of the fully mobilizing large units and units along routes which were ascertained by prior reconnaissance to be uncontaminated. However, the terrain will often be so contaminated that it will be difficult to establish such routes. In these circumstances the personnel and equipment will have to proceed, without the means of radiation reconnaissance and antichemical protection, from areas with very high levels of radiation (concentration of poisonous substances-OV) or cross these sectors en route. Naturally the personnel will join the units unfit for combat, or will have received large doses of radiation (contamination). In addition, the lack of recording devices might result in the inability to determine the degree of radiation received.

The way out of such a situation, as we see it, is that a certain part of the antichemical protection equipment should not remain in the warehouses of the large units and units, but should be handed over to institutions, enterprises, and kolkhozes, so that the latter could then issue the equipment to the reservists subject to call at the time of a threat situation or in case of necessity. The reasoning behind the advance transfer of these means is also justified by the principle of deconcentration of materiel supplies.

From our point of view it is necessary to deconcentrate not only the antichemical protection resources and part of the radiation and chemical detection equipment, but also clothing, by having the institutions, enterprises, and kolkhozes issue the latter directly to those subject to military call-up, with the stipulation that the uniforms be kept in special bags at the place of residence.

There need be no apprehension regarding loss or premature use of part of the clothing. Experience shows that storing such supplies in warehouses (bases), which in turn require the maintenance of a large staff and expenditures for upkeep of the building, costs the government sizeable amounts, even if we rule out the possibility of spoilage. Issuing this equipment to persons subject to call-up, and holding them responsible for it, will cost a great deal less. The management personnel of the enterprises (institutions) and the military

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

commissariats will periodically check the issued equipment.

The system of hospitalizing irradiated military personnel also warrants attention. It is known that the army does not have adequate hospital facilities for accepting and taking care of irradiated personnel, as will be required for elimination of the consequences of a sudden enemy attack. Apparently it will be necessary to send the casualties to civilian medical establishments. However, the mass of the civilian population that received combined injuries will also be going there, and there might not be any vacancies. This question must be carefully thought out by specialists, and the necessary decision should be made.

In our opinion, it is essential to examine such matters as the maintenance, even in peacetime, of fully staffed chemical protection sub-units in large units of reduced strength. As is known, during full mobilization a division must set up six or seven reception centers for personnel and equipment, and in each one of these, posts for medical and special treatment. Besides, the division, as it is presently staffed, does not have at its disposal the appropriate sub-units, nor are there any under the subordination of the army commander. Practically speaking, a division is not capable of conducting radiation, chemical, and bacteriological reconnaissance of its own concentration area, and the army commander cannot carry out these measures in the interests of the field command, army units, and in the interests of the army as a whole. There are no means for setting up dosimetric examination of the arriving personnel and equipment that was mobilized from the national economy. We consider it expedient to propose the following:

- besides a chemical protection company, the divisions at constant readiness should have a special treatment company that would be equipped with all the necessary materiel and equipment as one of the motorized rifle companies; the combat readiness of the division will not be decreased by this, and thus, even in peacetime, the cadres will be ready that will subsequently be the backbone in the formation of special antichemical protection sub-units;

- in divisions of decreased strength a chemical protection company should be maintained, composed of a platoon of radiation and chemical reconnaissance and two special treatment platoons, each of the latter setting up a special treatment post; regiments should maintain radiation and chemical reconnaissance platoons comparable in composition to similar platoons in regiments at full strength;

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

- in peacetime the army should have a full-strength separate radiation and chemical reconnaissance company and an army chemical-protection battalion, composed of three special treatment companies.

* * *

The combined-arms army of a border military district, deployed at a distance of 900-1000 km from the probable area of military operations during the initial period of war, can make up the second echelon of the front, since the main blow of the enemy ground forces will be absorbed by the troops located in the zone near the front. Consequently the army will receive simultaneously the tasks of fully mobilizing the large units at decreased strength, and at the same time, have the large units at constant readiness execute a forced march to the area of combat operations, with subsequent immediate engagement from the move (from the march).

Because of the possibility that large railroad centers may be put out of commission, and also because of the difficulty in effecting transport, caused by the difference in the gauge of Soviet and West European railroads, it is impossible to depend on railroads alone for the transport of the troops at constant readiness. The execution of a combined march can be accomplished only under more favorable conditions. There is also a possibility of shifting separate large units, especially from the second echelon, after they are brought to full strength, by air, using military air transport. It is most probable that, as a rule, the army will have to carry out a march of 1000 km on its own.

In our opinion, it would be expedient to assign to the army a zone no less than 100-150 km wide for executing the march. In such a zone it would be possible to use up to six to eight routes (two for each division) for troop movement, and two routes for the field command of the army and large units and units, and also to carry out a maneuver during an abrupt change in the direction of movement or in case of destruction of communications bridges and roads.

The march formation of the first echelon of the army may vary according to the number of divisions and routes in the zone of movement. In the beginning of the march (during the first march periods) it is expedient to have columns made up of similar vehicles. Tanks and artillery drawn by tracked vehicles must travel by independent routes. At the end of the march, possibly during the last day's march, depending upon circumstances, the march columns should be formed in such a way that the troops would be ready for instant deployment and commitment to battle. In our opinion, the missile [redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

units should follow the forward regiments; they should be moved to the front during the last day's march with suitable protection, and should then follow the advance guard of the forward regiments.

As a result of experience gained from training, we have concluded that a series of prescribed norms is subject to review appropriate to the demands of the initial phase of the war. Thus, a march of 900-1000 km, using our existing vehicles, equipped with additional fuel capacity, can be executed in four march periods: the first of 300-350 km, the second of 200-250 km, the third up to 250 km, the fourth up to 150 km. It would be expedient to execute the last march period at night.

In the situation under review, we feel that it would be expedient to call halts as follows: short (up to one hour long) - after every 4 to 5 hours of movement, long (not over 3 hours long) - after 8 to 10 hours of movement. During the last march period (at night) there should be a short halt only - of 1 to 2 hours' duration. Personnel should have a rest period after each march period of 8 to 10 hours.

In order to maintain minimum vulnerability to destruction by nuclear weapons, to insure maximum speed of movement and execution of maneuvers when bypassing contaminated sectors and various obstacles, it is expedient to maintain a distance of 50 m. between vehicles, 3 to 4 km. between battalions, and 5 to 7 km between regiments. Distances between companies (batteries) should be the same as between vehicles, because the prescribed distance of 100 m. only increases the total depth of the column, and as a rule is not maintained in actual troop movements.

Traffic control lines should be set up after 4 to 5 hours of movement, i.e., to have no more than two in each day's march. Setting up a greater number of control lines is not advantageous, because this limits, up to a point, the initiative of the commanders of large units and units, and eliminates the possibility of moving the column at increased rates of speed in sectors where the roads are of better quality, even if the routes of march are made available to the army for definite periods of time.

The commandant's service has the leading role in ensuring organized and timely transfer of troops. Careful study shows that during long marches the organization of the commandant's service presents certain difficulties, and the recommendations contained in the Manual of Commandant's Service, published back in 1953, does not completely fulfil modern requirements. The situation is made worse

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

by the fact that the army actually has no personnel or equipment in the table of organization for setting up a commandant's service, and the district commandant's service will not be deployed yet by the beginning of a march. In our opinion the tasks that the commandant's service is responsible for during a march by the troops in the initial stages of war, far exceed those in the above-mentioned Manual.

We fully share the viewpoint of Marshal of the Soviet Union M.S. Zakharov, expressed by him in the article "The Traffic Control Support of Modern Operations"[1] (O dorozhnom obespechenii sovremennykh operatsiy) for the organization of traffic control areas, their problems, and the forces and equipment that can be brought in.

However, we consider that it is possible to examine this matter in greater detail, under conditions of the execution of a long march by the army immediately after a sudden attack by the enemy. In our opinion, the commandant's service is confronted by the following problems in these circumstances: to maintain the established order during the movement of troops, to protect them from enemy air attack, to prepare bypasses and alternate routes for carrying out the maneuver, to assist in the elimination of the effects of an enemy nuclear or chemical attack (evacuation and deactivation of equipment and weapons; special treatment of personnel; repair damaged sections of roads and road structures) and to ensure troop control.

The composition of the army commandant's areas and the division commandant sectors should include motorized-rifle units and sub-units, antiaircraft defense, engineering, chemical, communications, special treatment and medical sub-units, and means for evacuating equipment.

The establishing of army commandant's areas and sectors eliminates the dispersal of forces and equipment along the entire route, and permits their concentration in sectors of special importance, depending on the presence of natural barriers. It would be expedient to set up individual, radio-equipped commandant's posts along the remaining sectors of the routes.

It is best to set up army commandant's areas in the more dangerous and difficult sections of the routes, where natural barriers block the entire forward movement zone of the army. The area commandant must be given a wide range of authority. All the commanders,

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

staffs, and troops passing through the commandant's area must execute the commandant's orders implicitly, and he, in turn, has full responsibility for the successful passage of the troops through a given sector of the route. In connection with this, one of the army deputy commanders should be appointed commandant of the army area, and the commandant of the division sectors should be one of the deputy division commanders.

The organization of a service in a commandant's sector of a division requires varying amounts of forces and equipment in each case. Generally speaking, for the movement route of a division, a total of up to three motorized-rifle battalions can be activated; these will be reinforced by the necessary engineering, chemical, and other sub-units, which are relieved of commandant's service duties when the division approaches the area of combat operations, or when they are replaced by forces-and equipment of the front.

Briefly, on the organization of control and communications during the march. In our opinion, in order to ensure troop control during a combat alert, it is necessary to set up, in the army, a forward command post (PKP), a command post (KP), and a reserve command post (ZKP) - the second echelon of the field command. It is not advisable to set up a rear area control point (TPU) before the field command and communications units are set up according to the wartime T/O. The officers of the rear services are located at the command post and the reserve command post. In the divisions at constant readiness, forward command posts, command posts, and rear area control points are set up; only command posts and rear area control points are set up in divisions that need further mobilization.

The forward command post, with the chief of the operations department in charge, must begin an immediate forward movement to the army departure line (into the area where the division at constant readiness is deployed), where he will control troop commitment. The command post and the reserve command post remain in the concentration areas where they were at the time of the alert. During the period when the forward command post moves forward, communications with the troops and the district staff are carried on from the command post. The army commander, with a group of generals and officers from the forward command post staff (four or five persons), remains at the command post in order to make decisions and assign tasks to the troops, but by the time that the troops of the first echelon begin to march he must be at the forward command post. The command post begins the forward movement from the concentration area during an alert only after the troops have been assigned their tasks. The reserve command post supervises mobilization and formation of new units from its

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

concentration area at the alert.

En route the forward command post moves along with the main forces of the division, deploys and sets up communications with the troops, the command post, and the headquarters of the front during halts and in rest areas. The command post of the army moves by bounds and deploys in spots that ensure the use of permanent lines of communications with the headquarters of the front, the forward command post, and the troops. The duration of the halts will be determined in each case by the time necessary to receive a situation report from the troops, transmitting orders to the latter, and reporting to the higher headquarters. Shifting the command post of the army in this manner may result in its lagging as much as 100 km. behind the troops and the forward command post. In order to avoid this during a march made in separate sectors, the command post and the forward command post must be on the move simultaneously, but for periods not to exceed 2 hours, due to the necessity of maintaining constant communications with the higher headquarters and the troops. After each march period the control points are placed in the area of dispoeition of the troops.

It is also expedient to have a forward command post and a command post within divisions on the march. They must move along separate routes and at a distance which ensures stable communications with each other.

Certain difficulties are encountered in ensuring communications during long marches. In order to conceal the troop movements, the radio nets of the marching troops cannot be used, and the permanent communications lines, even those on the territory of the Socialist Camp countries, may not be entirely familiar to the communication units of the army. These circumstances compel the use of commandant's service radiocommunications and mobile means, above all, helicopters. Radio stations of the commandant's service network are set up along specific lines. These stations operate by means of rebroadcast or relay of radio signals. As each unit passes a line, a pre-arranged signal is transmitted over the radio, which is duplicated by all the other stations and is received simultaneously by the control points of the division and army. The signals must be of a one-way type, without call letters or coded service phrases. During the first 24-hour march, radio communications of the commandant's service are organized using shortwave stations, during the second and third, ultra-short wave is used, and for the last day's march, communications are carried on with the assistance of radio-relay stations.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In carrying out a long march it must also be taken into consideration that the troops may suffer losses from the enemy weapons of mass destruction, and in some cases entire sub-units and even units may be put out of action. This is particularly pertinent in cases when the personnel receive large doses of radiation. In these conditions a new problem arises - replacement of personnel losses right during the march. The equipment not affected by the shockwave which belongs to the radiation-contaminated sub-units and units, can be used after decontamination. It would seem that in peacetime plans, provisions should be made to provide for the formation of sub-units and units (of the march company and battalion type) at the district level that could be shifted by air to the formations carrying out the march, and which could be used later as replacements for losses sustained during combat conditions.

* * *

The conditions under which a combined-arms army of a border military district that is moving forward from the depth is committed to combat, will always be determined by the nature of the combat operations carried out by the first-echelon troops of the front during the first days of the war, and it is rather difficult to predetermine them in advance. It is most probable that the army will be committed to combat directly from the march, and this is always attended by great difficulties and a series of peculiarities which require detailed study.

First of all, about the work of commanders and staffs in these conditions. It is apparent that the commander and the staff of the army will get the order from the front to commit the army to combat while moving (marching) at a distance of 250 km, or more, from the front line. Therefore the clarification of the mission, evaluation of the situation, making of the decision, planning, and informing the large units of the tasks will all be done in a very limited period of time, en route, without halting. Otherwise the commanders and the staffs may straggle behind the troops and lose control.

The situation is aggravated by the fact that at the present time the staff field equipment does not ensure operation on the march. Even the T/O of the commander of an army does not have an equipped mobile control point capable of ensuring operation and control of troops in a movement over a long distance. The creation from the forces and equipment of the troops of improvised mobile command posts, and the equipping of buses and GAZ-69 vehicles for operating in field conditions has indeed helped consfderably in cutting down the amount

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

of cumbersome equipment at the control points, and has made them more mobile, but it involves great expenditures, and does not basically solve the problem. The means of radio communication remain the same, and the cross-country ability of the automobile chassis does not conform to modern requirements.

While planning the commitment of the army to combat, and the carrying out of offensive operations in the entire depth, commanders and staffs must simultaneously define in detail the remaining segment of the march, taking into consideration the commitment of large units into combat and the conduct by them of an offensive, to inform the troops of the change in the plan of march, to control the troops continuously, to organize and maintain constantly coordination with the large units operating ahead, ensure replenishment of materiel supplies and fuel expended in the march, and to carry out reconnaissance of the enemy.

According to experience gained from the war games carried out in our army, it would be expedient to organize the work of the commanders and staffs in similar situations in the following manner:

Beforehand, when the army commander receives the district operational directive to march, he sends out an operational group to one of the headquarters operating ahead of the troops in the direction that the army is moving forward; their mission is to constantly provide information about the situation in the area of combat operations. The group should consist of five or six persons (officer-operator, intelligence officer, artilleryman, communications officer, chemical officer) and also a squad of radiation and chemical reconnaissance. It follows [one line missing] of operations and methods of transmitting information must be planned beforehand, in peacetime.

Inasmuch as the army does not have an air transport capability for distances of 900-1000 km, the operational group must move in motor vehicles, and the latter must move at a speed of up to 60 km per hour. Moving twice as fast as the army troops, the operational group will transmit the first information about the situation from the area of combat operations, at the time when the troops moving forward will be halfway to the concentration area, or the line of deployment. Moving along one of the basic routes, the operational group will be able to determine the condition of the route, and after arriving at the destination - can fully reconnoiter the area of command post disposition, and determine the presence of radioactive and poisonous substances and bacteriological agents. The

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

organization of communications with the operational group must be thought out in detail, utilizing intermediate radio stations, communications of the front, of the commandant's service, and, with the approach of the troops, mobile equipment.

When he receives directives to commit the army to combat, the army commander will make his decision by consulting the map. The army command post, headed by the chief of staff, must transmit the missions to the large units and control the forward movement of the troops, and with the forward command post the commander and the commanders of the large units move forward to the line of commitment to battle, in order to clarify the situation, organize coordination with the troops operating ahead, resolve the questions of support of commitment to battle, and possibly to change the original decision. The forward command post of the army must plan the operation quickly, resolve the questions of coordination and supply, and together with the forward command posts of the large units, assume control of the arriving troops. In connection with this, the forward command post must be very efficient, small in number, highly mobile, and must have adequate numbers of means of communications with the troops, the headquarters of the front, and of adjacent units.

The scope of work of the commanders and staffs under similar conditions requires detailed study, and a unified method of supervision and control must be worked out. Many are of the opinion that all these problematical questions should be formalized by the General Staff in official instructions or in a manual. We are of a different opinion. It is impossible to foresee all cases and possible variants under which the army may be committed to combat from the second echelon of a front, and to incorporate operating procedures in one official manual. It would be more beneficial to study similar problems constantly, check them out as much as possible during training exercises, and publish them as discussions. This method develops deep thinking and increases the general military outlook of the commanders and staffs.

It is another matter to resolve in a centralized manner questions regarding establishing a materiel base for command, communications, and technical support of commanders, staffs, and troops, with modern means of control. For instance, the critical need arises for the commanders of armies and large units to have mobile control points equipped with the newest, small, long-range radio stations, ensuring secure conversations without resorting to numerous conversation and signal codes. In the operations department of the army there should be a computer capable of quickly producing the data needed for the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

evaluation of the situation (above all the radiation situation) and arrive at a decision. A squadron of helicopters should be made a part of the army field command T/O, to implement troop control, for conducting radiation, chemical, and engineer reconnaissance, and for fulfilling other important tasks.

Another problem which needs to be solved is the method of recording the degree of radioactive contamination of the personnel. The commanding officer of a sub-unit cannot keep a written record for each soldier, especially during the frequent transfer of personnel from one sub-unit to another, and especially after hospitalization. It is apparently necessary to issue to personnel, individual, miniaturized devices of the "pencil" type, with coded indicators; this will exclude the possibility of independent reading of the radiation dosage received by the personnel themselves, but will permit the commanding officers to determine the true meaning of these doses with the aid of a corresponding decoding device (one to a company).

It is known that modern conditions for conducting a battle and an operation demand exceptional speed and maneuverability by commanders and staffs. Therefore it is necessary, even now, to change radically their style of work. Up to this time the staffs are producing many combat documents. Even though in the past few years they have eliminated some of the written documents, these same documents are now being worked out on maps, and often duplicate each other; this takes even more of the staff officers' time than before. Frequently the work of a staff is judged by the number of documents produced. This explains the fact that in all exercises a large number of additional officers is taken from the troops for work in the staff. As yet the troops do not have staff field service instructions which fulfil modern requirements. This also appears to be one of the reasons for a series of shortcomings in staff work.

The questions that we have raised call for thorough study during command-staff exercises, war games, and during the buildup of large units to wartime strength.

Some Questions on the Theory of Military Art

by

Colonel-General I. Gusakovskiy

In the pages of the first and second issues of the Special Collection, a sharp and fundamental controversy has developed concerning the most important questions of strategy, operational art, and tactics. Of particular interest are the contributions of those authors who raise new problems relating to the nature of modern warfare, the methods of conducting armed combat, the use in it of the various types of armed forces, etc. As a matter for discussion, we consider it necessary to express our opinion on a number of questions raised in the article of Colonel-General A. Gastilovich.[1]

The first question concerns the length of a future war. As is known, General A. Gastilovich advocates the idea of a "blitzkrieg", determining the direction of our military development in accordance with this. In his opinion we have "no need to fear the term 'blitzkrieg' just because this concept was compromised by the experience of past world wars. Under the conditions of nuclear war only 'blitz' operations can promise victory." With this basic argument in defense of the theory of "blitzkrieg", General A. Gastilovich cites the availability in the armament of modern armies of nuclear/missile weapons, by means of which entire countries can be put out of a war in its first days. This situation, as the article indicates, "will hardly evoke enthusiasm in the remaining countries for its prolongation." Therefore, the author concludes, "he who has withstood the first strikes, must and can conclude the war rapidly if he prepares his armed forces properly in peacetime."

---

[1] Special Collection of Articles of the Journal "Military Thought", /First Issue, 1960/

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Proceeding from the considerations cited above, General A. Gastilovich suggests a rather simple "concept of conducting initial operations under conditions of the European Theater". According to this concept a powerful retaliatory nuclear strike with weapons of megaton yield is launched at the beginning with the aim of putting two or three NATO countries out of the war. Following this, ground troop operations are developed which mop up the remaining enemy forces and occupy enemy countries. To conduct such operations, in the opinion of the author, not more than 30 to 40 divisions will be required. The concept indicated, "to the same degree, with certain corrections for geographical conditions, can also be applied in other theaters". In short, the substance of war in the concept of General A. Gastilovich boils down to border engagements of the opposing sides with a subsequent unimpeded advance of our troops onto the territory of the enemy.

In our opinion, such a point of view on the nature of armed combat does not conform to modern reality. We realize perfectly clearly that a future war unleashed by an aggressor against the Soviet Union will inevitably become a world war between the two contending social systems of the world. The basic means of waging the war will undoubtedly be nuclear/missile weapons, and the theater of military operations will be the entire globe. Therefore, it would be naive to think that such a war between coalitions of countries possessing tremendous military-economic power can be concluded by a "blitzkrieg", with one strike. It will be, without doubt, an intense, hard, and exceptionally fierce war with decisive political and military objectives. This is the kind of war for which we must prepare our armed forces in order to ensure the security of our Homeland.

One may ask, is it correct under these conditions to orient the military leadership toward a "blitzkrieg"? In our opinion, it is not correct. The theory of a "blitzkrieg" is calculated for a weak enemy, incapable of withstanding nuclear/missile strikes and continuing the war after huge materiel losses and human casualties. One cannot approach the evaluation of our probable enemy with such a yardstick. We must proceed, first of all, from the fact that in a future world war, if it is unleashed by the imperialists, we will have to fight against the coalition of a strong enemy who has at his disposal all the modern means

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

of combat and who is capable of recovering after the first nuclear/missile strikes are inflicted on him. To count on victory over such an enemy by a "blitzkrieg" is not to take into account the real relative strengths and potentialities of the opposing sides, but is to underestimate the aggressor. This is very dangerous. The stern lessons of history oblige us to prepare in the most serious manner for a hard and long war against a strong and crafty enemy. This, of course, does not mean that the third world war will necessarily assume a protracted character. Modern means of combat permit gaining victory over the aggressor in relatively short periods of time, for which we will strive. It may be that this war will in fact assume a fast-moving "blitz" character. However, this is improbable. The interests of assuring the security of our Homeland demand from us that in building the Soviet Armed Forces, we do not go to extremes and do not nourish the illusion of victory by "blitzkrieg" operations, but that we prepare in earnest for a protracted and hard war.

As is known, the theory of "blitzkrieg" is not new. It failed completely in the Second World War. Today it is advocated by various Western military figures who threaten to destroy the Soviet Union and other Socialist countries in a few hours. In this, these theoreticians rely basically on a sudden strike by nuclear/missile weapons. However, they do not allow for the fact that the Socialist Camp cannot only withstand the initial nuclear strikes of the aggressor, but can also give him the necessary reply. N. S. Khrushchev stated this well in his speech at the IVth Session of the Supreme Soviet of the USSR:

"Let us assume, however, that some country or group of countries could successfully prepare and execute a surprise attack on a power possessing nuclear and missile weapons. But, even supposing for a minute that the attacking side could successfully execute a surprise strike, could it really immediately put out of action all stockpiles of nuclear weapons and all missile equipment installations of the power suffering the attack? Of course not. The country suffering the surprise attack, if it is understood that the discussion concerns a sufficiently large country, will always have the potential to duly repulse the aggressor".

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

It is perfectly clear to us which countries N. S. Khrushchev had in mind. Apparently our enemies are also taking this situation into account, since in their camp voices are heard more and more persistently denouncing 'blitzkrieg", demanding a renunciation of the strategy of so-called "massive retaliation" and a switch to the creation and preparation of reserves of all types for the possible conduct of a long and protracted war.

On what basis must we glorify the idea of "blitzkrieg", which has been condemned by history, and elevate it to the rank of a theory which points the way of further development of the armed forces? In our opinion, the presence in armament of strategic nuclear/missile weapons still does not give us a sufficient basis to assert that the third world war will have the character of a "blitzkrieg." To propagate the idea of "blitzkrieg" under our conditions is not only dangerous but is also harmful, insofar as it disorients the military leadership in the building of the armed forces and in securing the defensive capability of our Homeland.

The second question concerns the numerical strength of the armed forces. The thought runs through the article of General A. Gastilovich that "for direct combat operations at the front neither in the beginning of the war nor during its course will such numerous ground armed forces be needed as was the case in previous wars?" The author believes that in a future war engagements of multimillion-man armed forces are excluded, and that victorious war can be waged with the forces of small, technically highly equipped armies.

To support his statements, the author advances the following arguments: 1) In modern war "nothing will arrive from the depth of the country in time", so it is impossible to build up forces in initial operations with fully mobilized large units. 2) The forces of the enemy remaining after the first nuclear strikes are inflicted cannot be numerous, and a numerically large army is not needed to crush them. Proceeding from these considerations, General A. Gastilovich proposes, for the conduct of initial operations in the European theater of military operations, to have a small number of various divisions (within the bounds of 30 to 40), organizationally represented by two fronts of 15 to 20 divisions each.

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

We cannot agree with such conclusions of the author on the numerical strength of armed forces in modern war. Their unsoundness is convincingly shown by Colonel-General G. Khetagurov in his article (Special Collection of Articles of the Journal "Military Thought" /Second Issue, 1960/), with which we are in complete agreement on this question. It seems to us that the judgments of General A. Gastilovich on the numerical strength of armed forces are an attempt to revive the well-known theory of waging war by the forces of small armies. Similar ideas have often been expressed in the foreign press, but they have not found practical application in the past, and do not find it today. Our enemies, as is known, are preparing for the deployment of rather significant ground, air, and naval forces in a future war and it would be a grave error for us to orient ourselves on waging war with small armies.

A future war, as we have already emphasized, is a world war between two powerful coalitions of states hostile to each other because of their social structures, it is a war of multi-million-man armies with numerous and complex combat equipment. As opposed to previous wars, a nuclear/missile war will be characterized by a still greater spatial scope, when in the literal sense of the word there will be no difference between the front and rear of a country, when the territory of countries will be turned into theaters of military operations. For conducting such a war, massive armed forces will be required, still larger than was the case in past wars. And this is completely natural, because the involvement in war of a large number of countries, the hugh spatial scope of armed combat, and also the necessity for recovering from heavy losses will inescapably lead to the quantitative growth of the warring armies, to a still greater degree than was the case in the past.

In our opinion, we should prepare our armed forces for just such a war. This, of course, does not mean that we must increase our army in peacetime. The defensive power of our country, N. S. Khrushchev indicated, is determined not by how many soldiers we have under arms or by how many people wear soldiers' overcoats, but by the firepower of our armed forces. At present, the Soviet Army possesses such combat means as to permit not only withstanding the probable enemy in case of attack, but also to strike back as

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

necessary. Under these conditions, a reduction in the numerical strength of the army will not prevent us from maintaining the defensive capability of our Homeland at the necessary level. Therefore, guided by the policy of peaceful coexistence, the Soviet Union is significantly reducing its armed forces on a unilateral basis, paving the way for an easing of the international situation and the strengthening of peace in the entire world. N. S. Khrushchev spoke of the reasons for the further reductions in our armed forces sufficiently convincingly at the IVth Session of the Supreme Soviet of the USSR. However, in reducing the numerical strength of the army, we do not at all count on waging war with small armies in the event that we are attacked. For conducting a victorious war, a significant increase in the armed forces and the deployment of a multimillion-man army will undoubtedly be needed. From these positions it is necessary to decide the questions of our further military development.

The third question concerns the methods of conducting military operations. The high degree to which troops are technically equipped, and the appearance in the armament of armies of nuclear/missile weapons undoubtedly introduces much that is new into the methods of conducting war. First of all, the role and assignment of various types of armed forces and arms of troops in wartime is substantially changed. A decisive role in modern war will be played by the missile troops, especially those armed with strategic missiles, and also by missile weapons of the other types of armed forces. At the same time, conventional types of armament will find wide application in war. Only by the combined efforts of all types of armed forces and means of combat can the assigned goals of a war be attained.

It is perfectly obvious that nuclear/missile weapons dictate a new approach to the conduct of both offense and defense. However, in the investigation of this question, one should not go to extremes for the sake of trying to find something new in military affairs. Thus, General A. Gastilovich asserts that "in the training of troops, it is necessary to reject decisively the cultivation of the principle of breakthrough of the enemy's prepared defenses" insofar as this "has ceased

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

to be the primary form of offensive actions, having yielded to meeting engagements and envelopment." We cannot agree with this assertion of the author.

In our view, breakthrough of the enemy's defenses remains as a type of offensive action under conditions of a nuclear/missile war, although it will not be executed in the same manner as in World War II. While in the past it was essential to concentrate a large number of forces and weapons to execute the breakthrough from a position of direct contact, and to conduct the offensive itself on the entire front and in close formations, in order to effect a breakthrough of prepared defenses under modern conditions this question will be solved differently. The primary means of breakthrough is now nuclear/missile weapons, with which the enemy's defenses can be broken to the entire depth in short periods of time and by subsequent swift operations of troops from the rear they can be broken through with a rush and the rout of the opposing grouping completed. In our opinion, the swift breakthrough of defense subsequent to nuclear strikes will be the basic content of offensive operations. Moreover, the offensive itself, as opposed to past wars, will be conducted in separate areas, at high tempos and with wide use of airborne troops and transport of troops by air.

It is quite clear that under conditions of a war of maneuver, meeting battles (engagements) with the enemy's reserves will occur very often, and also the execution of enveloping maneuver of troops with the aim of emerging at a considerable depth in the enemy's positions and capturing his most important areas (installations). Therefore, in training troops in peacetime it is essential to prepare them both for the precipitous breakthrough of the enemy's prepared defenses and for meeting engagements. To reject the mastering of the methods of breakthrough of the enemy's prepared defenses in the training of troops, as General A. Gastilovich proposes, means to consciously ruin the field training of troops and to lower their combat readiness.

Advancing the thesis that meeting engagements are the basic form of offensive operations, the author proceeds from the considerations that modern defense must be based "on the same methods of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

operation as offensive operations, i. e., on heated meeting battles and engagements." In other words, in the opinion of General A. Gastilovich, the operational methods of troops in both defensive and offensive operations will be identical. Lieutenant-General V. Baskakov arrives at approximately the same conclusion, declaring that under conditions of nuclear/missile warfare the distinctions between an operational offensive and operational defense are obliterated.[1] Consequently, says General A. Gastilovich, in the formation of operational defense one must reject the creation of defensive zones "because they do not justify their designation" and relegate the very term "stable defense" to the archives.

We cannot agree with such a definition of operational defense and operational offense: On this question we completely share the opinion of General of the Army P. Kurochkin, as stated in his article.[2]

Without doubt, linear defense along entire fronts has departed to the realm of the past. Its place will be taken, apparently, by highly maneuvered, swift defensive battles and engagements of a heated nature. The decisive role in defense will be played by nuclear/missile weapons which permit the defenders to disrupt completely the enemy's offensive and to assume the offensive quickly in their turn with the aim of completely routing the enemy. In this case, troop operations will most closely resemble an offensive against an enemy who has hastily turned to the defense, and in some cases also meeting battles (engagements).

The rejection of positional forms of combat in defense does not at all signify a denial of the firm retention of important areas and installations in the direction in which the enemy's offensive is

[redacted]

1.3(a)(4)

expected. It appears to us that under the conditions of nuclear/missile war, also, the structure of the defense, and accordingly, of groupings of troops, must answer the problem of retaining the basic areas of terrain in the probable directions of the enemy's offensive. In the interests of fulfilling this mission, nuclear strikes, troop maneuver and counterattacks and counterstrikes must be planned. We apply this proposition to tactical as well as to operational defense. Therefore, it seems to us that it is still too early to relegate the term "stable defense" to the archives. On the contrary, nuclear/missile weapons give it a new content, directed at attaining important results in defense that neither artillery nor aviation could give in the past. In this connection, neither is it possible to equate defense and offense. These two types of combat operations of troops differ in principle from one another not by the amount of nuclear weapons, as General A. Gastilovich stated, but by their goals and methods.

A few words about the planning of missile operations. General A. Gastilovich proposes the conduct of two types of missile operations by the missile formations of the VGK (Supreme High Command): operations with the aim of completely destroying the enemy's country and putting it out of the war, and operations in support of the ground troops. Missile operations of the first type must precede operations of the second type and subsequently be conducted parallel to them. In accordance with this, in the opinion of the author, among the missile formations of the VGK it is essential to have missile formations to carry out the mission of putting entire countries out of the war, and formations designated for operations in support of several fronts conducting operations in one strategic axis.

It appears to us that there is no necessity to plan the above-named two types of missile operations and, by the same token, there is no need to create corresponding missile formations for this. In our opinion, one missile operation must already be planned and prepared in peacetime with the mission of destroying the enemy's nuclear weapons, damaging his economic potential, disrupting the various types of transportation, and crushing his grouping of ground troops in the theater of impending operations of our troops. This mission

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

can be fulfilled simultaneously by one and the same missile formations of the VGK, together with the missile means of the fronts conducting operations on a given strategic axis. It is possible that under certain conditions it will be necessary to conduct an independent missile operation with the aim of completely destroying the economic potential of one of the enemy countries and putting it out of the war. But for this, the same VGK missile formations which will subsequently conduct operations in support of ground troops can be used. It is therefore inadvisable to separate the missile formations of the VGK artificially into two groups.

In conclusion, we wish to note that we welcome with great interest the publication of the Special Collection and the participation in it of authors who express their thoughts and proposals freely on extremely important problems of military theory. There is no doubt that the creation of this Collection will promote the further development of Soviet military art.

Increasing the Stability of Control of the Troops of a Front (Army)

by

Major-General M. Ivanov

The first issues of the Special Collection of Articles of the Journal "Military Thought" correctly state the problem concerning a review of the postulates of the theory of strategy, operational art, and tactics in light of the revolutionary changes which have come about in the realm of armament from the moment when nuclear weapons and missiles appeared on the scene. In the interests of the further development of military theory, we must decisively reject attempts to adapt old forms and methods of conducting military operations to new conditions, and we must work out comprehensively and profoundly the problems of modern combat and operations and the structure of the organizations pertaining to them, including the control organs.

As is known, the organizational structure of staffs is directly dependent upon methods of conducting combat operations and of equipping troops with the means of combat. At the present time, significant changes have taken place in armament, combat equipment, the nature of operations, and the methods of their conduct. Consequently, there should have been a corresponding change in the organization of staffs. However, this has not come about and in fact our operational organs of control, from the organizational standpoint, still remain at the level of the staffs of the World War II period.

In the interests of increasing the effectiveness of troop direction, the organization of operational staffs must, in our view, at least correspond to the following requirements:

--to ensure a capability for constant control of the readiness of missiles, aircraft, and nuclear warheads and of the location and movement of all objectives of nuclear attack;

--to preclude any lack of coordination in the actions of commanders of arms of troops and services; commanders of troops of the front (army) must work jointly with their immediate

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

subordinates in one place, controlling and coordinating their actions; chiefs of directorates and services must decide all problems together, and not in isolation from one another;

--to eliminate disunity in the processing of data concerning a situation; all information must be concentrated in one place, in one organ so that it can be immediately available to the commander of troops of the front (army);

--to unify control of the weapons of destruction;

--to promote sufficient viability in the control organs.

At the present time, the organizational structure of operational staffs is based on the same division of labor and distribution of functions in the staff as existed many years ago. In this connection, now as in the past, a great number of elements takes part in implementing control of the troops of a front: combined-arms staff with many independent directorates (departments), the artillery staff, the air army staff, the PVO staff, the engineer directorate and others. In their work, all these elements depend upon one another and are constantly forced to coordinate their actions. If these organs are located at separate control points, coordination of their actions, even in accomplishing simple tasks, seriously hampers the work of the front (army) staff and leads to an extremely great loss of time.

Consider, for example, the planning of operations. As is known, the staffs of all the arms of troops, special troops, and services take part in this process together with the staff of the front (army), and the planning is carried out on a broad scale. But despite this, it still is a single, centralized process. Although they act on behalf of the common goal of the operation, all services and arms of troops work disconnectedly. As a consequence, planning breaks down: the operational plan is worked out in one place by one organ, the plan for the combat use of missiles and the artillery is worked out by another organ in another place, the plan for the combat use of aviation is worked out by a third organ in a third place, etc. Because all these plans are closely tied in with one another and require constant coordination during their working out, the planning of operations extends over a long period of time.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

This principle of planning was tolerable as long as the factor of time did not play such a decisive role in the control of troops as it does at the present time.

The dynamic nature of operations and the striving of the opposing sides to seize the initiative will lead to one form of combat operations rapidly transforming into another without significant pauses. Those prolonged periods of preparation of operations, which now take place in our conduct of all types of training exercises, will vanish. Under these conditions, it is natural that staffs will be required to coordinate and execute an entire complex of complicated measures, which must be planned in short periods of time. Decisions must be implemented on a broad coordinated front, and very rapidly. Consequently, an urgent need arises to speed up and improve the process of planning. It seems to us, that in order to resolve this problem, it is advisable to have a single planning center in the composition of the field command of a front (army).

We carry out the direction of troops and the control of weapons of destruction in much the same manner as the planning of operations. At present, on the scale of a front, the combat operations of combined-arms large units (tank and motorized rifle troops) are under the immediate direction of the staff of the front (army), while the weapons of destruction are in the hands of the chief of the missile troops and artillery and his staff, of the commander and staff of the air army, of the chief of the PVO troops, and of the chief of the chemical troops. This situation also leads to great inconvenience in the control of troops and does not promote increased effectiveness in the work of the control organs.

We consider that unification of the functions of the direction of troops and the control of the weapons of destruction may prove to be not only beneficial but even extremely necessary.

In the work of the staffs, the rapid collection, processing and transmission of information materials to command echelons and troops become especially important. Today, it is extremely important to know at all times the exact location of all forces and weapons and their condition and readiness to fulfil combat tasks. For this reason, it is necessary that the staffs sharply reduce the time for processing information.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

However, the existing system for the collection of data on a situation is multi-staged. Information material, as formerly, is transmitted successively from one echelon to another: the regimental staff transmits information to the division staff, which transmits it to the army staff; it is only the army staff which informs the front staff of the situation. All directorates (departments), services and arms of troops engage in the collection of information at the scale of the front (army). Therefore, information on the situation is scattered among them. After reaching the front command post, the data on a situation are first studied and collated in the staffs of the arms of troops and the services, then they are reported and re-reported to various chiefs, and only after this are they reported to the commander. In order to have a complete picture of a situation, the front (army) staff and particularly the operations directorate (department), in addition to receiving information directly from subordinate staffs, is obliged to collect situation data from the staffs of arms of troops and from the services. Coming from various sources, many of these data are incomplete and contradictory, do not coincide in time, and require rechecking and clarification.

All this creates excessive red tape within the staff and finally leads to the fact that the collected and processed situation data do not correspond to the true troop situation at any given moment. In the army staff, the data lag behind by 1 or 2 hours, and in the front staff by 2 or 3 hours. The commander is deprived of the capability to influence the course of an operation in time, and often makes decisions according to a situation which, in reality, no longer exists.

In addition, the content of the information received by each service and arm of troops has much in common, and the requests for these data by various consumers create an extremely heavy load on subordinate staffs, upset them, and tear them away from the solution of other important and complex problems unnecessarily.

The necessity for all services and all staffs of arms of troops to collect information, which stems directly from the organization of the control organs, leads to the overloading of lines of communication, necessitates supplementary channels, and involves an increase in the expenditure of communications resources at control points; this in turn makes the staffs more cumbersome and less mobile. It should also be noted that all inquiries and reports on the situation and the operations of the troops are still made by means of message and radio signal codes, which greatly delays the collection and processing of information.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

It is perfectly obvious that such an information system has completely outlived its usefulness. In order to ensure rapid reactions by the command echelon and the staffs to a situation, it is necessary to centralize the collection and processing of information data. All information must be concentrated in one organ and be put on an overall map or screen. However, this can be done only after an appropriate reorganization of the control organs.

Intelligence should be considered separately. New demands are also being made on it, particularly on the process of collecting and processing data on the enemy. Carefully organized and unceasing intelligence work has become the guarantee of timely detection of enemy preparations for the use of weapons of mass destruction. Today, as never before, the combat readiness of troops and their ability to conduct successfully combat operations depend on intelligence operations. The fulfilment of all the tasks assigned to intelligence demands an even greater centralization of its resources, single control, and firmer direction. Without this, intelligence organs will hardly be able to play their part.

Even though this is obvious, the intelligence organs and their forces and means are still disconnected from the organizational standpoint. On the scale of a front, not only the intelligence directorate, but also the artillery staff, the air army staff, the engineer directorate, the chemical staff and others are engaged in intelligence. A similar situation exists in the staff of the army and in the staffs of large units. All these intelligence organs frequently work on their own, on behalf of only that arm of troops which they are called upon to serve, and if some of the information obtained by them does become the property of all the troops, it reaches them only after a very great delay.

It is completely understandable that such an organization of intelligence organs cannot, under modern conditions, ensure a high degree of effectiveness in the receipt of intelligence data. The role of this service has grown to such an extent that there is a direct necessity to combine all these organs into a single independent intelligence center, directly subordinate to the commander of troops of the front, and having all the means of intelligence at its disposal.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Therefore, under the existing organization of the field command of a front (army), the efforts of all its elements are disunited; this gives rise to frequent confusion in the operations of various arms of troops, complicates coordination of the efforts of the various means of combat, and creates great difficulty in the rapid assignment of their combat missions.

In order to eliminate these shortcomings, and to ensure stable control of troops on the scale of a front (army), it is necessary to centralize drastically the direction of troop combat operations. The organizational structure of operational staffs must be changed correspondingly.

It appears to us that from the standpoint of centralization of the control of troops and weapons of destruction, the reorganization of control organs must proceed by way of unification of all the directorates (departments) and staffs of the arms of troops and services which are concerned with the direction of troops into single control centers.

In accordance with this, it is advisable, in our opinion, to have within the composition of the field command of a front (army):

--a main command-planning center;

--a nuclear/missile center;

--an operations center;

--an intelligence center;

--a PVO control center.

The main command-planning center must be the basic working organ of the commander of troops of the front. Here must be united all the currently existing control organs of the staffs of arms of troops and the services which are concerned with the planning of operations and the direction of troops. All the planning of an operation must take place in this center only. Centralized control of all means of combat, including ground troops, missile weapons, PVO, and aviation, will also be carried out from here simultaneously. The complement of

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

this center will include generals and officers from all arms of troops and specialties. When located at the command post, the chief of staff of the front and all chiefs who are directly responsible for the direction of the operation must be located in this center together with the commander. For rapid analysis of the situation and decision-making, a single map of the operational and radiation situation, the aerial situation, and the situation of the PVO, and a map of the grouping and combat readiness of our missile weapons must be constantly maintained here. These maps should be mounted in a vertical position for observation, in the manner of the PVO screen.

In relation to the remaining echelons of the field command of the front (army), this center will be the directing organ. It should direct their activity in order to ensure rapid reaction of the command echelon to all changes in the situation.

The nuclear/missile center will be a united organ for controlling the weapons of destruction of the front. All the weapons of nuclear attack must be concentrated in the hands of the chief of this center, i.e. missiles of all types, bomber aircraft and others, which will undoubtedly improve and expedite their use.

Inasmuch as the overall plan for the use of nuclear/missile weapons will be implemented by the main command-planning center, the functions of the nuclear/missile center in this respect will consist of making all the essential calculations for the use of nuclear/missile weapons, calculations of the possibilities for neutralizing various targets, of the safe removal of our troops from the ground zeros of bursts, of the probable degree of destruction of the objectives, etc. In addition, it must keep track of the movement and readiness of the missile weapons of the front, maintain an operational record of the availability and receipt of missiles and the special charges for them, and maintain a graphic chart of their readiness.

The nuclear/missile center must have direct communications with all the weapons of nuclear attack and must coordinate all its work closely with the operations and intelligence centers which are the sources of information.

The operations center should engage in the collection and processing of data on the operational and radiation situation, decide questions of combat support, implement the transmission of combat tasks to the troops and control their fulfilment.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

All information on the location and operations of our troops and on the results of the use of nuclear weapons by both sides will be concentrated, summarized, and thoroughly analyzed in this center. This will permit the creation of the conditions for the uninterrupted processing of all data on the ground and aerial situations and will bring about completeness and a high degree of effectiveness in the collection and preparation of data, permitting decisions to be made rapidly by the commander of troops of the front (army). In order to achieve rapid processing of information, the operations center must have direct communications with all the formations of the front.

The activities of this center will be conducted through the chiefs of axes, who must process the data on the position of their troops on the appropriate operational axes and transmit commands received from the main command-planning center to the staffs of the appropriate formations (large units) for implementation.

Since our proposed organization of field command of a front (army) assumes the abolition of a number of currently existing services and directorates (engineer, chemical, and others) and the transfer of decisions on their problems to the operations center, the functions of this organ will be much broader than those carried out by the operations directorate. In connection with this, the operations center, as well as the main command-planning center, must have a complement of highly trained generals and officers from the appropriate arms of troops and specialties.

The intelligence center is assigned the collection and processing of all intelligence information. All the intelligence resources of the front are concentrated in the hands of this single organ; it must conduct intelligence work on behalf of all arms of troops and disseminate information concerning the enemy to all centers. For the nuclear/missile center, the intelligence center must keep an account of targets (objectives for nuclear attack), make an evaluation and general description of them, keep track of the movement of primary targets, calculate the most advantageous time and place for the delivery of nuclear strikes, pinpoint the coordinates of the targets and prepare the initial topographic and geodetic data. The chief of intelligence of the front should be the head of the intelligence center.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

This center must have direct communications with reconnaissance aircraft aloft, with radio reconnaissance means and with other important sources of intelligence information.

The PVO control center is designated for control of the PVO weapons, including the fighter aircraft of the front. Its mission will include directing the repulse of massed enemy aircraft and missile strikes. This center must have direct communications with all PVO weapons, with the staffs of aviation large units and with the intelligence center. It should be headed by the chief of PVO of the front.

We shall not stop to consider materiel, technical and other support. It appears to us that their organization must also be set up in accordance with the same principle.

This organizational structure of the field command of a front (army), will undoubtedly permit all its echelons to decide more effectively all the complex problems of troop control which are concerned with a common goal and a single concept. In addition, such an organizational structure of the operational staffs will correspond to a greater degree to modern methods of controlling troops, which are based on the use of the latest control equipment.

In our opinion, the organization of all subordinate staffs must also be built in accordance with this same principle.

In order to increase the flexibility of control, along with the proposed changes in the organizational structure of the field command of a front (army), it is necessary to review the means and methods of work of the staffs in the area of collection, analysis and transmission of information data.

Without going into a detailed description of this problem, we believe that the information system must ensure that all interested elements receive the data on a situation as the events occur. In order to achieve this, it is necessary to make some changes in the procedure for sending reports at the level of the division, army and front. Along with a periodic presentation, say 1 or 2 times a day, of the more substantial reports with a description of the positions and operations of the two sides which are now presented, it is essential to organize the transmission of short signals to indicate only the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

lines attained by the units of the first echelon and the nature of their combat operations ("I am advancing", "I am defending", "I am withdrawing", etc.). These signals must be transmitted by the staffs of large units every 30 to 40 minutes according to a strictly established schedule. In order to send these signals, the division staffs could take data from the battalions which come in automatically through the use of course-plotters (kursoprokladchik) and determine for every given moment only the precise location of the battalion command post (the center of the combat formation).

It must be supposed that this simplification of reporting and elimination of intermediate elements will permit the staff of the front to have precise data on the position of the first echelon troops 30 minutes after the units reach any line. Experience from wars and exercises indicates that these data, especially under complex situational conditions, are sufficient to enable the commander to react instantaneously to the course of events.

In this connection, reality requires the establishment of a procedure for transmitting information by which each command echelon can relay information on the position of its troops and the enemy directly to the next higher staff: the regimental staff to the army staff, the division staff to the front staff, and simultaneously to relay this information correspondingly to the division and army staffs also.

We have examined above only one of the questions of incongruity in the organizational structure of operational staffs due to the changed nature of combat operations. A second problem, which is directly related to the organization of control organs and which, in our opinion, is also in need of review, is the problem of control points.

The increased importance of uninterrupted control of troops provides a basis for assuming that in future operations staffs will be one of the primary targets of enemy action. The combatants will adopt every measure to disorganize the work of control organs and to disrupt the direction of troops. For this purpose, strikes by missiles or aircraft may be delivered, diversionary groups may be sent out, and jamming may be conducted against the means of communication. The capability of using nuclear weapons creates a real threat of instantaneous removal from action of entire control echelons and large bodies of troops. Therefore, the organization of operational staffs must be subordinated first of all to guaranteeing their vitality and ability to retain control in the most complex situation.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Under conditions of the mass use of nuclear weapons, this may be achieved by creating dispersed, more ramified, and constantly operative networks of control points to ensure rapid replacement of points which have been put out of action, and broad continuity in the control of troops.

In an operational element, the solution to this problem is reflected by the creation in formations of control points, command and forward command posts, and also rear control points. In this connection, it is believed that the existence of these points permits successful control of a large number of troops and weapons of destruction.

In our opinion, such an organization and echeloning of control points in the front (army) cannot sufficiently ensure their vitality under new conditions and, consequently, does not promote increased stability of control.

The creation of several points for the control of front (army) troops is justified only when each of them functions constantly, is fully independent and is capable of assuming troop control in the event that another point is destroyed by an enemy nuclear strike. Unfortunately, front (army) command and forward command posts, as they are at present constituted, do not meet these requirements. The basic reasons for this consist of the following.

In the first place, despite its numerical strength, the T/O of the field control of a front (army) does not in fact provide for the creation of two full-fledged control points. For this reason, only one independent control element, the command post, is actually created in a front (army). The forward command post is organized by using the forces and means of the command post. In its make-up it is usually a temporary and poorly organized control organ and, naturally, cannot fully provide the commander with firm direction of troops in the event that the command post is put out of action.

Secondly, the forward command post is not a constantly functioning control organ, because it is usually created only for the period of the conduct of combat operations. During the preparation for an operation, the generals and officers and the transportation and communications means designated for the command and forward command posts are usually located together at the command post.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

It must not be overlooked that the enemy will seek out and destroy control points, not only during the course of combat operations, but also during the period of preparation for an offensive and during the organization of defense. For this reason, it is quite obvious that with the personnel and the means of control of the command and forward command posts all located in one place, even for a short interval of time, there is serious danger of their simultaneous destruction and the actual removal from action of the entire control of the front (army), which can undoubtedly cause complete disruption of the control of a large number of troops.

Thirdly, the very fact of the creation of a forward command post predetermines its place and role in an operation. As is known, it moves forward on one of the axes, as close as possible to the front, so that the commander can feel the "pulse" of the combat and observe it to the extent possible. Almost all the chiefs of directorates (departments), services, and the commanders of arms of troops arrive at this post together with the commander, all communications channels are switched here, and in this manner the center of gravity in the control of troops is transferred entirely to the forward command post. Thus, because of this, the command post, with all the means of control, becomes an unnecessary attribute and actually participates only indirectly in the direction of troop combat operations.

We consider this to be nothing more than a vestige of the past. The tendency to move the commander and his observation post forward to the troop combat formations was justified in the years of World War II, when operations developed relatively methodically, when front formations and armies had a comparatively shallow operational formation /4 or 5 words missing/ means of control permitting direct influence on the course of operations from command posts far removed from the troops.

Now, however, when the nature and conditions of conducting operations have changed sharply, such a situation cannot be acknowledged as correct. In the future, the basic method of conducting combat operations will be mass nuclear/missile strikes, carried out with the aim of simultaneous mass destruction, not so much of troops located on the line of combat contact of the opposing sides, as of objectives located in the rear area. The center of gravity of combat operations under these conditions can shift from the zone of combat contact to the depth of the disposition of front (army) troops. The former

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

linear formations and operations of troops will also disappear, engagements will be conducted on axes and in separate areas, and operations in the rear area will frequently begin before the advance of ground troops from the front.

It is perfectly obvious that in making decisions in such a situation it is insufficient to be guided by the picture of combat on one axis. In order to react both correctly and quickly to the course of combat operations, the commander must constantly be aware of the entire situation. But this is only possible if, during the course of the entire operation, he is supported by the basic personnel of the front staff who are located at the command post in the area of the main grouping of troops. If, however, during the course of an operation, the commander is located primarily at a forward command post on only one of the axes, he will be unavoidably detached from the overall situation and will be unable to influence not only the development of the operation as a whole but even the most important changes which may arise at any moment away from the forward command post. Under these conditions, it is difficult to say where the presence of the commander will be required first--forward, on one of the flanks or in the rear of the front's troops.

Deep disposition of front (army) troops, particularly of reserves, missile units, airborne troops, and the possibility of committing large units to battle in a hurry from the depth also make the forward move of the commander and the forward command post senseless, because in essence it causes him to be detached from the main forces. In the control of troops, emphasis must now be placed not on personal observation of the field of combat and on personal contact of the front troops commander with the commanders of large units, but on control from a distance. Of course, even under modern conditions, the commander must visit certain axes for the immediate direction of battle, particularly during the critical moments of the development of an operation. But this will take place only incidentally and will not be the system to which we adhere today.

It is also essential to consider the fact that the evolution of means of control is proceeding in the direction of complex automation of the processes of direction of troop combat activity, and it must be assumed that staffs will soon be equipped with automated systems. However, the relatively large size of these systems and the complexity of their apparatus limit their maneuverability and permit their effective use only at the command post.

[redacted]

1.3(a)(4

[redacted]

1.3(a)(4

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Fourthly, the necessity for an auxiliary control point will often arise in the course of an offensive operation as well as in defense, especially when we succeed in breaking up the enemy's operational formation and in cutting off part of his troops from the main grouping, and when the operation therefore disintegrates into a number of engagements. However, at present it is impossible to do this because of the limited capabilities in forces and means of the operational staffs, which are capable of creating only command and forward command posts from their complement.

And, fifthly, as has already been mentioned, as a result of changes in the situation, critical moments may arise on individual axes in an operation, requiring the personal presence of the commander and his involvement in the direction of troop combat operations. But the existing organization of control points and the means of communications and movement available to the staffs do not permit the commander to move rapidly to these sectors of the front. The forward command post is obviously not suited to accomplishing such tasks since it is too cumbersome, insufficiently mobile, and it is impossible to conceal its location in the vicinity of the enemy. However, there is no other organ for this purpose in a front or army.

Another important condition in increasing the viability of control points is their reliable security (okhrana), defense, and combat support. The constant threat of the use of nuclear weapons against control points and the increased possibilities of an attack on them by mobile units of enemy ground troops, diversionary groups, and airborne troops indicate the necessity for having sufficiently strong special organic security and support units for the protection of staffs.

During World War II subunits and units from the troops were usually used for the preparation, support, and, frequently, also for the defense of control points. This led to disengaging combat subunits from the accomplishment of important tasks at the immediate front and was not justified. As a rule, temporarily detached subunits and units were not suitable in their organization, equipment, training, and experience for accomplishing the tasks of preparing and supporting control points. The productivity and quality of their work was low, despite the fact that a large quantity of personnel and equipment was detached, part of the equipment was not used because of the impossibility of using it in the preparation of control points, and work was performed separately and was not united under a single command.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The situation concerning the security, defense, and support of control points is also in approximately this same state, even at the present time. The security and service regiment provided for by the T/O&E and attached to the front staff, and the battalion attached to the army staff do not have organic, engineer, chemical, and other special subunits at their disposal. This situation, as in the years of the last war, again leads to the fact that it will be necessary to use temporary and untrained special line units and subunits for the preparation, support, and servicing of control points.

Entirely different results can be achieved if these subunits are united and if on the basis of them, special units are created, equipped with the necessary weapons, equipment and the other standard items required for the combat support, servicing, and preparation of control points. The personnel of these units who are trained in advance will also acquire experience. On the whole, significantly greater effectiveness in the use of these same forces and means will be achieved and the organization and conduct of the security, defense, servicing, and support of control points will be greatly improved.

The problem of the direction of the entire security service for control points and of the maintenance of the required order in them is still decided by us in the old manner. Up to the present time, apart from the staff commandants, many staff officers who are insufficiently trained and inexperienced in this respect engage in this work, while having more than one function.

The growing volume of activities and the broadening functions of the commandant's service (komendantskaya sluzhba), as well as the necessity of carrying it out constantly, have drastically elevated the role of this service; it has now acquired the importance of one of the main elements in troop control. This circumstance requires centralization of the direction of the commandant's service, the placing of a strong independent organ at its head, and the subordination to it of all the forces and means assigned for the security and preparation of control points. In our opinion, only with this condition is it possible to resolve more purposefully and effectively the important problems of security and defense, of antiatomic protection, engineer preparation, and the concealed placement and transfer of control points and constantly to maintain the strictest order in their disposition areas, all of which will directly affect the viability of control organs.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Therefore, all these arguments permit a restatement of the conclusion that the existing organizational structure of operational staffs does not provide for the creation in a front (army) of a ramified network of control points which in turn does not promote an increase in the flexibility and stability of troop control. The organization of operational staffs, it appears to us, must be such as to ensure the creation of not less than two permanently operative full-fledged control points in a front (army) for all forms of combat operations and to provide the opportunity for the commander, in certain cases, to personally and directly participate in the direction of troops in the most important sectors.

For this purpose, it is essential, in our opinion, to have two independent control organs in the composition of the field command of a front and army.

The first is the staff of the front (army), including the basic complement of the field command and all the above-mentioned centers. On the basis of it, it is necessary to develop the command post of the front (army) as the primary control point, headed directly by the front (army) troop commander.

The second is the staff operations group (organic). This control organ must be somewhat smaller in its composition than the staff but must have an organization similar to that of the staff. As an independent control organ, the group must have its own organic means of communications and transportation in such quantity as to make it capable of assuming complete control of all the troops of the front in the event that the command post is put out of action. On the basis of the staff operations group, regardless of the situation, a second permanent control point of the front (army) must be created and headed by the deputy front (army) troop commander. Its title and designation will be determined each time by the specific conditions of the situation. Therefore, during the preparation for an offensive operation and in defense, this will usually be an alternate command post, but during the course of the operation it can become an auxiliary control point or can carry out the functions characteristic of the forward command post.

In peacetime, the personnel of the staff operations group should be located and worked in the appropriate control centers, in order to facilitate the work and perfect the skills of the officers. During

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

the training of staffs, this operations group must be prepared and knitted together as an independent control organ.

For the transportation of the commander and his deputy to any particular axis where their personal intervention in the direction of troop combat operations may be required, it is essential to have specially allotted control vehicles in the T/O&E of the staff of the front and the staff operations group.

For the security and combat support of control points, it is advisable to create special units and subunits and to include them in the T/O of the field control of the front (army). In our opinion, they should be called commandant's units (komendatskaya chast). It appears to be advisable to use organic commandant's regiments and separate commandant's battalions as the organizational basis. For servicing the command posts and rear control point of the front, it is essential to have a commandant's regiment for each of them; for servicing the staff operations group of the front and the command post of the army, to have separate commandant's battalions.

For direction of the commandant's service and of the security, defense preparation, and support of control points, it is essential to create in the staffs commandaturas (commandant's groups) with a complement of 5 to 8 officers headed by the commandant to whom the commandant's units and subunits must be subordinated. These will be organic, independent, and influential organs which possess the necessary forces and means and are capable of maintaining order at control points and of directing their relocation, security, and defense under any conditions.

The daily activity of the commandaturas must be carried out through permanent duty commandants. In this connection, and also on the basis of the proposed changes in the structure of staffs, we consider it advisable to abolish the operational duty officer in the staffs, particularly since he is no longer in a position to fulfil functions concerned with the collection of situation data which he has been charged with to the present time.

The presence of organic commandaturas will permit the concentration of the direction of all measures of security of control points in one element and in one place, will bring order to the commandant's service,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

and will significantly elevate its authority. In addition, this will release many chiefs and officers of staffs from their involvement in the organization and direction of the commandant's service and will give them the opportunity to spend more time on their immediate duties.

We propose a broad study of the questions which have been raised and a more rapid realization of the necessary changes in the structure and methods of work of control organs.

COUNTRY : USSR

SUBJECT : MILITARY THOUGHT (TOP SECRET): "The Organization of Antimissile Defense", by Colonel V. Savko and Colonel N. Maksimov.

DATE OF INFO : December 1961

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article entitled "The Organization of Antimissile Defense", by Colonel V. Savko and Colonel N. Maksimov.

This article appeared in the 1962 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1962 First Issue went to press on 29 December 1961.

Headquarters Comment: Military Thought is published by the USSR Ministry of Defense in three versions, classified RESTRICTED, SECRET and TOP SECRET. The RESTRICTED version has been issued monthly since 1937, while the other two versions are issued irregularly. The TOP SECRET version was initiated in early 1960. By the end of 1961, 61 issues of the SECRET version had been published, 6 of them during 1961.

The Organization of Antimissile Defense

(According to foreign views)

by

Colonel V. Savko

Colonel N. Maksimov

Under modern conditions, a wide variety of means can be used for the delivery of nuclear strikes against troops in a theater of military operations and against the objectives of a country's military potential: piloted aircraft, ballistic and cruise missiles, artificial earth satellites and spacecraft. This variety of attack weapons, which has a great range of speeds, and flight altitudes, and an enormous range of operation, makes it necessary to examine the question of combatting them in a new way.

The ability of modern attack weapons to deliver strikes, from low levels, from the stratosphere and, in the near future, from space, has produced a need for the broadening of the scope of antiair defense. Antiair defense is developing into antiair and antispace defense.

By contrast to the atmosphere (vozdushnoye prostranstvo), which has limits at a certain altitude, space (kosmicheskoye prostranstvo) is boundless. The limitless range of modern aerospace attack weapons, their freedom of maneuver (their strikes can be expected from any direction) and the possibility of their combined use both against troops and against the military objectives of a country, make it necessary to establish a single system for antiair and antispace defense.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

The tremendous progress in the development of aerospace attack weapons has made necessary a revision of views on defense.

It is known that during the past few years the USA has spent about 35 billion dollars on the creation of a system of antiair defense for the North American continent. The "Sage" semiautomatic control system has been set up, depending upon three radar lines constructed in the northern part of the American continent and possessing the necessary means of communication and electronic computers. Active defense has been based on the employment of antiaircraft missiles and of interceptor fighters armed with guided "air-to-air" missiles.

The development of strategic missile weapons has thrown doubt upon the expediency of these huge expenditures. The USA has stopped the development of interceptor fighters and significantly reduced work on the creation of new classes of ground-to-air and air-to-air guided missiles, and has reviewed and reduced the original plans for the formation of squadrons of "Bomarc" antiaircraft missiles for the antiair defense of areas of the country.

At the same time, having proclaimed a doctrine of "terror" (ustrasheniye), the USA and its NATO allies had to ensure that there would be no possibility of the destruction of their own strategic aerospace weapons, which could occur as a result of the first enemy strike.

With the appearance of nuclear/missile weapons, the means of attack immediately and abruptly determined the means of defense. It has become necessary to create weapons and systems for defense against ballistic missiles, and in the near future against space weapons as well. Passive methods (dispersal, concealment underground of the launching mounts of one's own missiles, constant retention in the air of units of one's own bomber aviation) have not eliminated the need to establish effective systems

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

of antimissile defense, despite the complexity of the problems which this has caused and their obviously enormous cost.

Work in the field of antimissile defense is being conducted in the USA, Great Britain, Canada and other countries. The leading role belongs to the USA.

The Americans have already been working for more than 10 years on the solution of the problem of antimissile defense (protivo-raketnaya oborona-PRO). The best scientific resources and a considerable number of the largest American industrial companies have been brought into work in this field.

The detection, recognition, interception and destruction of long-range missiles are problems that are hard to solve, because of the great speeds and altitudes at which missiles fly, and because of the small dimensions of the target (the nose cone of the missile). Moreover, the enemy can take various steps to make the detection and interception of the missile's warhead difficult, or measures to confuse the PRO system.

Three phases of a missile's flight trajectory are examined during theoretical investigations into the possibilities of combat with missiles. The first is the active phase, during which the engines and the equipment of the guidance mechanism of the missile are in operation. The missile moves through this phase in a comparatively short time, not more than 2 to 3 minutes.

The second is the middle or free-flight phase. The beginning of this phase of the trajectory is marked by the point in space at which the missile engines are cut off and its nose cone is released automatically. From this moment the nose cone of the missile moves along the trajectory of a freely thrown body (in the first approach to an ellipse).

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

The third phase is the final phase, during which the nose cone of the missile enters the dense layers of the atmosphere. Its duration is determined by the altitude of the active layer of the atmosphere, which is about 100 km. Methods for combatting missiles are being worked out in the USA in accordance with these features of the flight of missiles.

The detection of missiles in flight. Timely detection of missiles in flight is one of the most important elements in a PRO system. For warning of a surprise attack using missiles, means for the early detection of the latter were required first of all. Using the newest achievements in the field of electronics, the Americans devised powerful radar sets with a range of operation of several thousand kilometers.

The increase in the range of operation of radar sets was achieved by increasing the power of the transmitters and the sensitivity of the receivers, by setting up improved antennas, and by using the technical and scientific achievements attained in the field of radar in the last few years. Great successes were achieved in this respect, thanks particularly to the application of methods of a new science - the theory of information.

Experimental models of the American PRO radar sets had a power of from 2 megawatts (the AN/FPS-17 set) to 10 megawatts (the AN/FPS-35 set). The vacuum tubes which are being developed at present allow the power of the transmitters to be increased to 20 to 50 megawatts. Thanks to the use of molecular amplifiers, the sensitivity of the receivers is increased tenfold and a hundredfold . This also permitted an increase in the range of action of the sets.

The use of huge directional antennas and of new methods for the separation of reflected signals

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

made it possible to increase the range of action of a set without significantly increasing its power, both by concentrating the energy emitted in the required direction and by improving conditions for the reception by the antenna of reflected signals. Based on the use of new antenna devices, the AN/FPS-49 and AN/FPS-50 radar sets were devised in the USA, with a range of action of up to 5400 km against a target as small as that which is represented by the nose cone of an intercontinental ballistic missile.

Besides such sets, whose range of operation is still limited by the zone of line-of-sight (zona pryamoy vidimosti) the possibility of using "Tepee" sets employing the [redacted] back-scatter probing (vozvratno-naklonnoye zondirovaniye) method. In principle, this method permits the detection of missiles while they are still in the active phase of their trajectory. But such sets can only determine the azimuth and, with little accuracy, the distance to the target. It is therefore proposed to use the "Tepee" set to supplement detection systems using AN/FPS-49 and AN/FPS-50 sets.

As well as radar sets, infrared equipment may be used to detect missiles. By locating such equipment on the ground it is very hard to provide the great range required. When it is located in space the situation changes fundamentally. First of all, the great obstacle of atmospheric absorption of the infrared radiation disappears. Secondly, the missile can be detected in the active phase of its trajectory, when it is a powerful source of infrared radiation.

Already in 1957 experiments were conducted in Canada which showed the possibility of detecting missiles with infrared equipment, at a range of up to 1600 km. In 1958 the Americans were able to track the flight of the third Soviet artificial earth satellite,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

flying at an altitude of about 400 km above the earth, with an infrared tracking device of the firm "Aerojet". Later, models of infrared devices with even greater ranges of operation were produced. For example, the range of operation of a multipurpose gyroscopic head, built by the "Martin" firm in 1959, is estimated as several thousand kilometers when the launch of a missile is detected from space and several hundred kilometers when using the head to aim at artificial earth satellites.

In this way, thanks to the enormous progress in the field of radio-electronics, the problem of detecting missiles in flight is being successfully resolved.

Recognition of missiles. In the development of a system of antimissile defense, a great deal of attention is devoted to solution of the problem of recognition of the missile's nose cone from among the various types of interference and of dummy targets.

There are many methods which make it possible to hamper the destruction of the missile in flight and to disorganize the PRO system. These methods include: covering the missile nose cones with a protective layer which sharply reduces the reflection of electromagnetic energy;--the use of dummy targets which camouflage the flight of the actual nose cone;--the use of active jamming of the radar sets of the antimissile defense system.

One of the simplest ways of creating dummy targets is to break up the missile airframe as soon as the nose cone is separated in the middle section of its flight trajectory. All of this presents complex problems for the PRO in finding methods of combatting equipment which creates radio-electronic interference and in developing methods of identifying targets, i.e., of determining their true nature. The general problem of recognition of dummy targets in the middle phase of a trajectory has not yet been solved by the Americans, even theoretically.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

One opportunity for recognition occurs during the flight of the nose cone and of its accompanying complex of dummy targets in the final phase of the trajectory--in the atmosphere. During reentry into the atmosphere the movements of the dummy targets and of the missile warhead change in different ways, their infrared radiation varies in intensity and spectral characteristics, and other phenomena appear which simplify the solution of the problem of recognition.

By studying the nature of changes in speed it is possible to distinguish the missile nose cone from the dummy targets. The missile warhead will brake more slowly than the dummy targets and will have a higher speed. However, since it passes through the dense layers of the atmosphere in a very short period of time (10 to 12 seconds) this method of recognition is not acceptable. Recognition of a target by this method will occur too late and the defense system will have no time to destroy the nose cone which has been picked out.

During entry into the atmosphere, both the nose cone and the dummy targets accompanying it heat up and give off infrared rays, a shock wave builds up in front of them, and an ionized gaseous trail behind them. However, the use of these phenomena for recognition of the nose cone is unacceptable for the same reason.

The most effective method for recognition, used by the Americans in the "Nike-Zeus" system, consists of the use of special radar sets with very high discrimination, capable of receiving data on the whole group of targets during flight while it is still in the middle phase of its trajectory. The signal reflected from a flying object makes it possible to obtain some idea of the change in its reflecting surface during flight, of its dimensions, and even of its shape.

If signals from flying nose cones and from various dummy targets are studied in advance, the knowledge of their "signatures" can be used to solve

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

the problems of recognition.

In order to put this method to practical use, the Americans registered the signals reflected from the nose cones of their own missiles while these were being tested at firing ranges. Signals from the nose cones of Soviet missiles launched into the central part of the Pacific Ocean were also registered. In 1961 launchings of "Titan" missiles with devices for the creation of interference and of dummy targets began.

A recognition radar set is used in conjunction with an electronic computer, into whose memory are fed the characteristic signals which correspond to the flight of actual nose cones. This same machine receives data on the signals of all objectives observed from the recognition set. Comparison of these data in the machine permits recognition of the missile nose cone in a group of dummy targets.

Means of detection and recognition. At the present time the basic means for the detection of missiles in flight are ground radar posts with ultra-long-range detection sets, which make up the Ballistic Missile Early Warning System.

The BMEWS system includes three radar posts, located in Thule (Greenland), Clear (Alaska), and Fylingdales Moor (Britain). The range of operation of the radar sets installed at these posts exceeds 5000 km.

In addition to the detection of missiles in flight, the BMEWS system permits the approximate determination of the probable objective of an attack. The performance of the second task is simplified by the fact that, after the engines stop working, the warhead of a missile follows a ballistic trajectory, to determine which it is enough to make several fixes and to determine the impact point of the missile by extrapolation of the trajectory.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK [redacted] 1.3(a)(4)

The total warning time--i.e., the time from the moment the alarm is given until the missiles strike their targets--provided by the BMEWS system is from 15 to 17 minutes.

The shortcomings of the BMEWS are that it does not cover all the probable missile launching areas and that it can be neutralized with the aid of special equipment or disorganized by the creation of dummy targets. In addition, the system is expensive, cumbersome, stationary, and could be destroyed before missiles are launched against objectives on the territory of the USA.

The realistic way toward an increase in warning time lies in the use of special earth satellites with infrared or radar equipment which permit detection of missiles in the active phase of their trajectory.

Satellites with infrared equipment for the detection of missile launchings are being developed in the USA under the "Midas" project. As is known, in October 1961, the "Midas-4" satellite recorded the launch of an American "Titan" ballistic missile from Cape Canaveral. The satellite passed over Florida at an altitude of more than 3000 km. The launching was detected within 90 seconds of the launch of the missile, but the detection signal was transmitted within 90 minutes, when the satellite passed over California, where there is a station for the reception of signals from such satellites.

In the experimental satellites, detection signals are to be recorded, together with time details, and transmitted to the earth on the commands of the tracking stations which have so far been built. In a future satellite operational system, the signals must be transmitted immediately as the launchings are detected. A network of interconnected earth satellites will be used for this purpose.

Besides detecting launchings of missiles, "Midas" satellites can probably determine, at least approximately,

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

the direction of their flight, in order to provide plots for the sets of the BMEWS system.

An operational system of "Midas" satellites should be set up by the Americans before 1965.

Satellites with radar sets are still in the stage of scientific and experimental development, and their establishment, probably as multipurpose spacecraft, is possible after 1965. Thus, one of the projects, proposed by the "Ryan" firm, envisages the creation of a space system of early warning with satellites, on which a whole system of radar sets for the detection and tracking of the ballistic missiles and spacecraft of the enemy is installed.

The employment of artificial reconnaissance satellites in a PRO system increases the possibility of detecting missiles. With the help of satellites a missile can be detected within 1 to 2 minutes of its launch.

Interception and destruction of missiles. The task of intercepting and destroying missiles consists of preventing them from exploding in the area of defended objectives. The interception and destruction of a missile is considered most effective during the active phase of its flight trajectory (during the acceleration stage), when the missile presents a large target and is flying at a comparatively low speed. Interception during the middle phase of the trajectory may lead to the destruction of the missile at a great distance from the defended objective. However, in both the first and second cases, means of interception with a great range of operation and highly accurate guidance are required. The development of such means involves great technical difficulties. In the USA means for intercepting the nose cone of a missile in the final phase of its trajectory, when it enters the atmosphere, have been brought, in practice, to the stage of flight tests. Interception at this phase of the trajectory

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

permits the use of weapons with a comparatively short range of operation.

Because of their great approach speeds, the interception of missiles is only considered possible on collision or collision-intersection courses. A nuclear warhead is used to destroy the nose cone of the missile.

Taking into consideration the comparatively small radius of destruction of even a nuclear warhead when it explodes outside the dense layers of the atmosphere, other probable methods of destruction are being studied in the USA. Special project "Glipar" was devoted to this question, having as its goal the study of the possibilities of destroying missiles or of rendering them harmless, including those which, at today's level of technology, appear highly problematical, but which may prove effective in the future, when our knowledge of these questions has increased considerably.

The "Glipar" project studied the possibility of destroying missile nose cones with small fragments or particles of hard substances, with gases, plasmas, electrical charges, radiation and with the action of various fields. The use of hard particles, which, when they hit a nose cone which is moving at high speed, may inflict considerable damage upon it, proved to be the most effective means.

One of the experiments to study the impacts of hard bodies, flying at great speeds was conducted in 1961 in the ballistics laboratory at the Aberdeen Proving Grounds, and in this, metal balls 7 mm in diameter brought about the almost complete destruction of the wall of a 105 mm artillery shell.

Evidently in connection with this, the Advanced Research Projects Agency of the U. S. Defense Department advertised for bids for the development of a PRO system (Project ARPAT) in which the warhead of a missile would be destroyed with "shrapnel" shells when it enters the atmosphere.

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

As for the other methods of destruction studied, their realization at the existing level of technology was found to be in practice impossible, although research in this direction is still continuing. As an example, one can mention the method based on the use of so-called "lasers" --powerful sources of monochromatic infrared or light radiation. Such lasers already make it possible to obtain a narrow beam of radiation which has an impulse power of tens of megawatts, although it is true that this is of very short duration, measured in microseconds.

The use of similar means from the ground is hardly possible, even taking into account their future development and a future manifold increase in the energy of their destructive impulse. The basic obstacle here is the absorption of energy by the atmosphere. This obstacle can only be overcome by installing improved lasers on spacecraft with a high coefficient of effectiveness and great power. While impulses of modern lasers can lead to the heating of material to a surface temperature of several thousand degrees, in the future one can foresee the possibility of burning through the structure of the nose cone of a missile or satellite, which can prevent the explosion of the missile's charge or can lead to its destruction during reentry into the atmosphere.

Means for the interception and destruction of missiles in the active and middle phases of their flight trajectory are in the stage of theoretical development. Earth satellites are considered the most promising means for the performance of these tasks.

The development of a space antimissile system is being conducted in the USA under the "Bambi" program. Such a system could provide defense on a global scale, but requires the use of several thousand satellites. In order to bring this system into use it is necessary to reduce significantly the cost of orbiting a kilogram of payload and to bring this down to several dollars or, at the most, tens of dollars. The destruction of missiles can be carried out by homing satellites (the RBS project) or by satellites armed with homing antimissile

1.3(a)(4)

[redacted]

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

missiles of the "space-to-space" class (the SPAD project). Both these projects are still in the initial stage of development. In both cases an infrared guidance system is considered to be the most suitable for homing.

Besides automatic interceptor-satellites, for anti-missile and antispace defense, it is also proposed to use piloted interceptor-satellites with a man on board. For the present the development of such satellites is being pioneered by some American firms.

In the USA it is considered possible to create PRO space weapons in 1966-1967.

For the interception and destruction of missiles in the final phase of their trajectory (during reentry into the atmosphere), the Americans, starting in 1955, have developed several PRO systems. The "Nike-Zeus" system, which permits the interception and destruction of missiles at altitudes of up to 150 km and at ranges of up to 320 km, has received the greatest development.

Up to the present day, experimental models of the radar set for this system, of the electronic computer, and of experimental models of the "Nike-Zeus" antimissile missiles have been constructed.

Although the "Nike-Zeus" PRO system has been under development for many years, and although some of its elements could be put into mass production, adoption of the system as armament is being delayed. In the U.S. Defense Department there are doubts of the reliability and effectiveness of the system, particularly in its ability to distinguish missile nose cones from dummy targets.

Moreover, the cost of setting up such a system, even for the defense of only the most important cities and objectives on United States territory, is calculated in billions of dollars (according to some data it may reach 4 to 15 billion dollars).

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

Taking these circumstances into consideration, the U.S. Defense Department and the President of the USA have reacted to the proposals of the army to begin production of the components of the system before the completion of its comprehensive tests, including firings against "Atlas" type combat missiles, with a certain caution.

Flight tests of the experimental model of the missile began in 1959 at the White Sands proving ground. The second step in the tests, including the launching of a complete three-stage missile with a guidance system, but without a nuclear warhead, is being completed at present at Point Mugu on the west coast of the USA (the state of California). The third step, during which live firings of "Nike-Zeus" missiles will be carried out against "Jupiter" and "Atlas" missiles, is planned for the middle of 1962. The "Atlas" missiles will be launched from Vandenberg Air Force Base and the "Nike-Zeus" missiles from Kwajalein Island in the Marshall Islands in the Pacific Ocean. A complete complex of components for the system is being built on this island, including underground launching mounts for the missiles, for radar sets (target acquisition, target recognition, and tracking of the target and of the missile), and the necessary computers, launching and auxiliary equipment.

After the speech of the Minister of Defense of the USSR, Marshal of the Soviet Union Comrade R. Ya. Malinovskiy, who reported to the XXII Congress of the CPSU on the successful solution in the USSR of the problem of destroying missiles in flight, the American command decided to speed up the tests and the beginning of production of the components of the "Nike-Zeus" system. The time limits for conducting live firings of "Atlas" intercontinental ballistic missiles for interception by "Nike-Zeus" missiles are connected with the decision of the President of the USA on the resumption of nuclear weapon tests in the atmosphere. The first tests, with the detonation of nuclear warheads on "Nike-Zeus" missiles with a yield of from 2 to 5 thousand tons are planned for the end of December 1961 or January 1962. The first firings against "Atlas" missiles, in which both the "Nike-Zeus" missile and the target missile will be fitted

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

with nuclear warheads, are planned for February 1962. Without waiting for the conclusion of the tests, the Defense Department and the President of the USA decided to ask for appropriations to begin production of components of the "Nike-Zeus" system in 1962. It is planned to arm the first PRO batteries with them in 1963.

The organization and conduct of PRO. All means of antimissile defense will be subordinate to the Air Defense Command of the USA. It is planned to use the units and subunits of the PRO in the first place for coverage of missile bases and strategic aviation bases. The use of the "Nike-Zeus" system in combat is carried out in approximately the following manner. A target (missile), crossing the fan-like beam of a BMEWS system radar set, reflects electromagnetic energy which is picked up by the receiving apparatus of the set.

Information on the target, contained in the reflected signal, enters the target selection system and is then transformed into numerical form and fed into a computer.

The selection device enables the missile to be picked out among the numerous reflections which result from atmospheric phenomena, the Northern Lights, meteorites, artificial satellites, etc.

The computer calculates the approximate trajectory of the missile's flight and determines the objective which is probably under attack, for target acquisition by subsequent elements of the defense system. In addition, the computer formulates a message on the detected target, which is fed into the communications line in numerical (coded) form, and arrives at the US Continental Air Defense Control Center. The report shows the calculated trajectory and the probable impact point of the missile.

A special warning system has been set up to transmit data on the appearance of missiles. At each post of the BMEWS system there are data units (datchik) and means of communication which provide instantaneous transmission of data.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

In the antiair defense control center the message which has been received is decoded and evaluated and the data received are compared with information which has arrived from other sources.

In accordance with the indications received from BMEWS posts or at the command of the antiair defense control center, the antimissile subunits are put in a state of combat readiness.

The "Nike-Zeus" system consists of a series of defensive centers, which provide protection for particular objectives with the aid of several batteries of antimissile missiles. The fire of these batteries is controlled from the defense center, which has an acquisition radar set and a computer for processing both the data arriving from BMEWS posts and those from this set...

The acquisition set has an operating range of about 1600 km and carries out a repeat (povtornyy) detection of the missiles approaching the defense objective. For this it is necessary for the nose cone of the approaching missile to be in motion within the operating sector of the set for about 20 seconds. Information on the targets goes from this set to the computer of the defense center and is used for target acquisition and for the distribution of targets among the antimissile missile batteries.

The battery is the basic subunit of the system. It has a target recognition set, a target tracking set and several sets for tracking the antimissile missiles. Apparently a battery will consist of 24 antimissile missiles with the necessary launching and auxiliary equipment. All the equipment of a battery is stationary.

The target recognition set picks out the missile nose cone from among the dummy targets. Recognition of the target is based on a comparison of the signal characteristics reflected from the target, with the known characteristics of various objects which have been fed into the memory of the computer. As a result of such a comparison, the

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

data on the real target are singled out by the exclusion of false information. Approximately 30 seconds is taken for target recognition, after which the missile nose cone is taken over by the target tracking set.

When the target is being tracked, its trajectory is defined with greater precision and the requisite data are fed into the device for controlling the launch and guidance of the antimissile missiles. The guidance computer calculates the flight trajectory of the antimissile missile and determines the point at which it will meet the target. At the necessary moment the command for the launch is given and this ignites the engine of the first stage of the antimissile missile.

After the missile is launched, data on the flight of the target and of the missile continue to be continuously fed into the computer of the tracking system, and on the basis of these, commands are evolved for the guidance of the antimissile missile to its target. This device is a digital computer capable of performing 200,000 arithmetical operations per second.

The intercept computer also determines the moment for the detonation of the antimissile missile and generates the command for the explosion, which is then transmitted to the missile by the set which is tracking it.

It is considered that about 100 seconds are needed to prepare the antimissile missile for launching, to launch it, and for it to enter the interception area. To carry out the series of operations in intercepting and destroying a missile warhead with a speed of 8 km/sec., approximately 2 min. and 40 sec. are taken by the "Nike-Zeus" system. During this time the missile warhead will travel approximately 1300 km. The interception and destruction of the missile warhead is effected in the final phase of the trajectory at an altitude of about 150 km.

From all that has been said one can conclude that so far the USA does not have an organized PRO system or

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

effective means for combatting missiles. Many problems connected with recognition, interception, and destruction of the missile in flight still must be settled.

The establishment of antimissile defense involves huge expenditures of materiel which can only be afforded by states with a developed industrial-economic base and a large network of scientific-research institutions. The widest development of work on antimissile defense has therefore been achieved only by the USA. Meanwhile, in connection with the great expenditure on these tasks and the difficulty of resolving the technical problems of antimissile defense, some American military specialists are calling for the development, above all, of strategic attack weapons -- long- and intermediate-range missiles, strategic aviation and an atomic fleet -- as a means of "deterrence".

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "Defense of the Operational Rear", by Major-General Yu. Novikov.

This article appeared in the 1962 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1962 First Issue went to press on 29 December 1961.

Headquarters Comment: Military Thought is published by the USSR Ministry of Defense in three versions, classified RESTRICTED, SECRET, and TOP SECRET. The RESTRICTED version has been issued monthly since 1937, while the other two versions are issued irregularly. The TOP SECRET version was initiated in early 1960. By the end of 1961, 61 issues of the SECRET version had been published, 6 of them during 1961.

The critique of the 1961 Carpathian Military District exercise referred to herein was disseminated as [redacted].

Defense of the Operational Rear

by

Major-General Yu. Novikov

The equipping of the Soviet Army with missile/nuclear weapons and other modern equipment has compelled us, in recent years, to reexamine, as is well known, many questions of the theory of military art. In particular new principles of the organization and activity of the operational rear have been worked out and put into practice. However, in the process of carrying out this great work, which is directed toward the further perfecting of the operational rear, the defense of the operational rear has, unfortunately, not been studied in sufficient depth.

Meanwhile, in modern conditions of carrying out armed conflict, this matter has acquired great significance. In this article we shall examine two questions of this complicated problem; namely, the defense of the rear against ground forces of the enemy and antiair defense of installations of the operational rear.

In examining the defense of the operational rear, it is necessary to consider two propositions: the striving of the probable enemy to disorganize the rear of our troops and the changing character of modern operations, and the results of this and the conditions of work of the operational rear.

As a result of study of the views of the probable enemy, the conclusion may be made that in future operations the neutralization and destruction of the most important rear area installations and disorganization of the work of the rear will be achieved by carrying out strikes with missile/nuclear weapons and conventional means of destruction against our rear area installations, and also by wide use of operational and tactical airborne landings for the purpose of carrying the struggle into

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

the operational depth , destroy depots of nuclear weapons, break up the maneuver of reserves, and disrupt the work of the rear as a whole. A number of sabotage-intelligence groups will be sent into the rear of our troops, obviously, with the tasks of accomplishing various types of sabotage, attacking rear installations and sowing panic among the population.

The opinion is expressed abroad that it is advantageous to operate against the rear of the enemy with airborne landings or sabotage-intelligence groups; even small groups of saboteurs are able to disrupt the work of front missile-technical bases and thus degrade, or at least significantly weaken, the force of missile/nuclear strikes and greatly disorganize antiair defense of troops. In exactly the same manner the action of sabotage-intelligence groups and airborne landings against bases and front communication routes can hamper, and at times completely disrupt, the supply of materiel means to troops.

Modern operations are distinguished by their large scale. They develop on a wide front and in great depth with combat operations connected with mutual breakthroughs of the opposing sides developing simultaneously and into the depth of the troop disposition, which creates very complicated conditions for the work of the operational rear. The rapid tempos and the maneuvering character of combat operations lead to more rapid movement of the struggle into the operational depth, into the depth of army and front rear areas.

The fact that there will not be a solid front in modern conditions, has great significance for the work of the operational rear. Combat operations will develop on separate axes, and, consequently, the operational rear will not have before it the dependable barrier "wall" of the solid front, under cover of which it operated in the past. To this must be added that the troops of the first echelon, advancing on separate axes,

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

will not normally be diverted to the defeat and destruction of enemy groups, which are left on the flanks and in the rear. This task will now be accomplished by the forces of the second echelons and reserves.

Enemy groupings which have retained their combat effectiveness, and which are left in the rear of our troops, can temporarily block communication routes, carry out raids on important rear area installations, and thus complicate the situation to a significant degree. It is necessary to remember that the combat operations of our troops can develop on the territory of a country in the aggressive imperialistic military bloc, and it is fully possible that some part of the population ill-disposed toward us will carry out an active role in the rear of our troops.

In solving the problem of defense of the operational rear, it is essential to bear in mind the degree of importance of a number of installations and those forces and means which can be used for their defense.

There are 8 to 10 missile-technical bases of a front, or 3 separate missile-depot battalions, and missile fuel dumps, located and functioning in the operational rear. The importance of all of these installations is unquestioned. At the front missile-technical bases the assembly of the missile-carriers and nuclear warheads, the mating of missiles and the storage of reserve (zapas) missiles of the front are performed; from these bases they are transported to armies and to missile large units. The reserve of missile/nuclear weapons located at front missile-technical bases ensures fulfilment of further tasks of the front and the subsequent offensive operation. Moreover, the reserve of nuclear means is stored at bases, and the reserve of an aircraft guided missile is stored at antiaircraft missile-technical bases. However, the forces and means which are at the disposal of all the enumerated installations are sufficient

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

for the organization of defense against an attack of only a small group of the enemy.

Rear front and forward front bases must also be considered in the number of important installations of the operational rear. Other rear units and establishments — technical, medical, and transport — are also grouped in the area of deployment of front bases, as a rule.

A deeper echeloning of reserves of materiel means, carried out in the course of the change of the basic principles of organization of the operational rear, would undoubtedly be a useful measure. But it is necessary to bear in mind that now about half of all front reserves are located at forward and rear front bases. This increases the dependence of the armies on daily delivery of materiel means from front depots. It follows that even a short interruption of front communication routes can lead to the breakdown of the planned support of troops of the first operational echelon of the front.

Field pipelines, whose most vulnerable points are the pumping stations, have great significance in supplying front troops with fuel. The protection of the pipelines, stretching for hundreds of kilometers, and also of the pumping stations, is obviously quite complicated. However, this task is entrusted to the personnel of the pipeline brigades, who do not have sufficient forces for this task.

For carrying out regular delivery of materiel means, evacuation , and maneuvering of reserves, it is necessary to have a developed network of railroad and automobile communication routes. If it is considered that in a front there are not less than two railroad communication routes, three or four basic front military automobile communication routes, and several lateral railroad and automobile routes, then

[redacted] 1.3(a)(4)

the difficulties of the defense of front communication routes throughout their extensive length become apparent. Moreover, in the rear area of the front it is also necessary to defend the main communications links of the front and the General Headquarters of the Supreme High Command with their powerful radio, radio-relay and telegraph communications centers.

And finally, in the rear area there will usually be 6 to 8 hospital bases with 15 to 20 thousand wounded in each, which would no doubt be objects of attack by enemy sabotage-intelligence groups.

During the preparation for an offensive operation, when troops in a tight grouping occupy a relatively stable position, there are more favorable conditions for defense of the rear. In the course of the operation, especially during high tempos of advance, the main mass of forces and weapons, and in particular of antiair defense, moves behind the troops, and the rear area of a front remains without any protection. This is explained by the fact that rear area installations of the front, by the nature of the tasks they fulfil, must work in the same place for a rather long time. The mobility of the main rear area installations must be considered far from satisfactory. Therefore, front missile-technical bases are moved once every two or three days, forward front bases, once every four or five days, and rear front bases are moved only once during a front offensive operation.

Thus, in modern operations the conditions of work of the rear will be significantly more complicated than in the last war, and the role of rear support will increase sharply. Now the success of combat operation of troops, as never before, has become dependent on reliable and prompt rear support. One of the decisive conditions for dependable and uninterrupted rear support of troops is the viability of the rear, i.e., the preservation of its ability to support troops

[redacted] 1.3(a)(4)

in a complicated combat situation. Therefore the problem of defense of the rear has become one of the most critical problems, and if it is not solved there will be no guarantee of the success of the work of the rear, and along with this, the guarantee of success of the operation being carried out.

In these fundamentally altered conditions of the functioning and significance of the operational rear, the old, obsolete concepts, characteristic of the last war, unfortunately still survive: In agreement with these concepts, many persons consider that the entire grouping of rear area installations is to be protected by the operational troop formation, and, therefore, under no circumstances, are appropriate forces and means to be allocated for the defense of the rear, which is required to defend itself with its own forces and means. We are already accustomed to the expression, which in our opinion is trite: "the guarding and defense of the rear are carried out by forces and means of the rear", which, as a rule, is laid down in documents regulating the organization of these questions in the course of operations.

It is necessary to mention that in a number of theoretical works the question is raised of the insufficiency in the rear area of forces and means for the organization of its defense and protection. Thus in the fundamental work "The Rear Services in Modern Operations", it is indicated that "front and army rear units and establishments are spread out over a large area and have limited forces and means, so they are not in a position to organize reliable defense of the entire rear area. The accomplishment of this task is possible only by the utilization of combat units and large units of the front (army)" ... 1

1. The Rear Services in Modern Operations. Publishing Office of the Staff of the Rear Services of the Ministry of Defense, Moscow 1959, PP 261-262. 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

However let us turn to the practice of the large operational exercises of the last few years.

In exercise "Don" (1960), no large units for the defense of the rear were provided for among the troops of the Don Front. Exactly the same situation occurred in the inter-academy exercise carried out by the Commander-in-Chief of the Ground Forces in February 1961. In this exercise only one motorized-rifle regiment was designated for defense of the operational rear, from the combined-arms army of the second echelon of the front; it was returned to the army when the army was committed to combat, with the result that the rear area of the front was left without any forces and means of defense at all.

In the recent front two-stage operational-rear services exercise of the troops of the Carpathian Military District (July 1961), once again no troops were designated for the defense of the rear. As a result, the rear area of the front, with all the reserves of nuclear weapons, antiaircraft missiles, materiel, and many rear services units remained without any means of defense.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Let us examine briefly the question of defense of the operational rear from enemy air strikes. With full justification it can be said that the amount of forces and weapons usually designated are clearly inadequate for direct antiair defense of large rear area installations. Let us examine two examples from the experience of operational exercises of 1961.

In the above-mentioned inter-academy exercises (February 1961), only one antiaircraft missile regiment was designated for the antiair defense of stationary depots of the Central Front, located 400 to 600 kilometers from the troops and at large railroad junctions; naturally it could not screen all rear area installations. As a result, the "enemy" carried out nuclear strikes with impunity against the rear area front bases and large railroad centers.

In the operational-rear services exercises of the Carpathian Military District, the chief of PVO of the 2nd Front, possessing sufficient forces and means for antiair defense of the principal areas of disposition of the troops and front rear area, did not organize the defense of the most important installations of the rear, concentrating the main efforts on protection of the troops. After the intervention of the leadership this condition was corrected to some extent. For protection of the rear area of the front in the departure position, 25 percent of the antiaircraft missile means of the front, front fighter aviation, and part of the forces of the 7th Army of the PVO of the Country were allocated.The antiair defense of rear areas was also strengthened by the means of the PVO screening the troops of the first operational echelon and the TO & E means of the troops of the second echelons and reserves.

Analyzing this decision, it is necessary to remark on two aspects. Firstly, the main installations in the rear area of the front (the rear area front base and its separate, forward front base, two mobile missile-technical bases, and two separate antiaircraft missile battalions) were screened only by fighter aviation; antiaircraft missile units were not designated for their defense at all.

1.3(a)(4)

[redacted] 1.3(a)(4)

Secondly, installations of the army rear and the missile-technical bases close to the troops of the first echelon of the front were in favorable conditions, since they were in fact screened by the overall system of PVO of troops of the first echelon.

This example shows that in the period of preparation for the operation, the army rear as a whole is protected from strikes from the air, while protection of a number of the most important installations of the front rear area is not assured.

The chief director of the exercise pointed out at the critique that when the troops go over to the offensive, the PVO means of the armies and divisions move forward along with the troops and the antiair defense of the rear area of the front is greatly weakened. In spite of this, the strengthening of the antiair defense of the rear of the front after the transition of the troops to the offensive was not provided for in the plan of the PVO troops of the front. A most important failing, if not a defect, in the system of antiair defense of installations of the operational rear, is concealed herein, in our view.

In the pages of the Collections of Articles of the Journal "Military Thought", completely contradictory views have been presented on the most important question of the defense of the rear: whether a gap occurs between the system of PVO of the troops of the front and the system of PVO of the Country during the course of a front offensive operation.

Marshal of the Soviet Union Comrade S. Biryuzov, in the article "Antiair Defense in Modern Warfare and Trends in Its Development",[1] considers that "toward the end of an offensive operation, a significant gap may occur between organic antiair defense and Antiair Defense of the Country."

1. Collection of Articles of the Journal "Military Thought", No. 3 (58) 1961, P. 10

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

Marshal of Artillery Comrade V. Kazakov, in the article "Troops of Antiair Defense of the Ground Forces in Modern Operations",[1] on the other hand, indicates that "in reality no 'gap' arises".

The importance of this question in connection with the problem under examination in this article is that in this gap are located such very important installations of the rear as the regulating railroad junctions, part of the front missile-technical bases, the rear area front bases, and railroad and automobile communication routes of the front.

The experience of command-staff operational exercises, and in particular the operational rear services exercise in the Carpathian Military District, confirms that this gap does in fact exist, and that as the front advances, the main part of the means of antiair defense of troops also moves, with the result that the already limited forces of PVO of installations of the operational rear are reduced. The control of these means is complicated by the fact that toward the morning of the third day of the offensive operation, as occurred in the exercise of the Carpathian Military District, the majority of antiaircraft missile units protecting installations of the front rear area are located at a distance of 100 to 360 km from the front command post.

Thus, it may be considered that the operational rear is almost completely deprived of the forces and means required for the organization of ground defense of the most important rear area installations, and its antiair defense, usually conducted by limited forces, is not assured, especially in the course of the operation.

1. Collection of Articles of the Journal "Military Thought" No. 4 (59) 1961, P. 14

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

This is why we consider that, in present conditions, it is necessary to support fully the proposals of Marshal of the Soviet Union Biryuzov — during the advance of the ground forces to a depth of 250 to 300 km, to widen the zone of responsibility of antiair defense of the country or of a border large unit of PVO by moving their borders forward behind the advancing troops, with simultaneous movement of part of its forces for protection of new installations.

A number of measures must be adopted in order to assure the viability of the operational rear. For this, first of all, it is necessary to have special units and large units for defense of the operational rear. Such a proposal is suggested by the experience of World War II, when, in a significantly less complicated situation, special units of the Ministry of Internal Affairs were placed with combined-arms armies and fronts. Of course, it must be mentioned that the units carried out combat against sabotage-intelligence activity in the rear of the troops, and fulfilled obstruction functions, but did not carry out the defense of the most important installations of the front rear area from the ground enemy. At the present time we need large units and units which will be able to provide defense of the most important installations of the rear, above all front missile-technical bases, rear and forward front bases, antiair defense of rear area installations from low-altitude strikes, and to carry out combat with airborne landings and sabotage-intelligence activity in the rear area of the front.

In our opinion, it is necessary to have these units and large units in cadre form in peacetime, with short periods of mobilization and buildup. The above-mentioned organic units and large units of defense of the operational rear, naturally, will not be able to fulfil all tasks of the defense of the rear, but will become the backbone of the forward means of this defense. In specific conditions, depending on the situation in the operational rear, the commander of troops of the front will assign supplementary forces and means from among the combat large units to the jurisdiction of his deputy for the rear.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Secondly, it is necessary to solve the problem of antiair defense of the operational rear. In our opinion it is necessary to determine accurately the tasks of antiair defense of troops for the protection of installations of the rear. It is especially important to think over thoroughly, and provide for the coordination of, the forces and means of antiair defense of troops and of antiair defense of the country in relation to the operational rear, so that in the course of an offensive operation the boundary of responsibility for antiair defense of the country is promptly carried forward behind the advancing troops.

Thirdly, it cannot be expected that defense of the rear will be fully provided by any sort of allocated or organic forces and means. It is of utmost importance to increase the defensive capability of rear units and establishments themselves, equipping them with close antitank defense and means of defense from strikes by the enemy from the air at low altitudes. It would also be advisable to have organic observation and warning of enemy air activity in the main rear services units and large units.

Fourthly, it is necessary to organize precise control of all forces and means which provide defense of the rear. For the solution of this problem, in our opinion, two measures must be carried out: the creation of a unified system for the defense of the operational rear and centralization of control of it. Under the direction of the deputy commander of front troops for the rear, a unified system must provide defense of the rear from the ground enemy, antiairborne defense combat against sabotage-intelligence activity of the enemy in the rear, warding off low-altitude air strikes, and protection of the rear from means of mass destruction.

[redacted] 1.3(a)(4)

[redacted]
1.3(a)(4)

The necessity of strict centralization of the control protection, defense, and guarding of the rear was reaffirmed in the operational-rear services exercise in the Carpathian Military District. The chief director of this exercise properly pointed out that even the limited forces allotted to organic antiair defense for the defense of installations of the operational rear, quickly became uncontrolled because of their separation from the control point of the commander of troops of antiair defense of the front by a distance of 300 km or more.

We consider that it would be advantageous to combine the control of guarding, defense and protection of the rear in the hands of the assistant commander of the rear of the front for these problems, and to create in the headquarters of the rear of the front a special section for guarding, defending and protecting the rear, freeing the first department of the staff of the rear from those functions. It must be remembered that the deputy of the commanding officer of front troops for the rear has an unusually large amount of work in directing the operational rear. It is known that in the rear services of the front there are up to 500 rear services units, large units, and establishments, spread out over an enormous territory, which, in the course of a front offensive operation, reaches 400-600 thousand square kilometers.

In solving the problems of the control of all the forces and means of defense and protection of the rear, it is interesting to examine the pertinent experience of our probable enemies. Thus, for example, in the combined-arms large units and field army of the USA, it is proposed there will be a center for control of the rear, of which one function will be the direction of the activities of the organs of the rear for defense and protection of the rear areas and elimination of the effects of nuclear attack. In this center of control there is to be a special section for defense and protection of the rear.

[redacted]

IRONBARK

1.3(a)(4)

[redacted] 1.3(a)(4)

In the new conditions of conducting operations, questions of the guarding and defense of the rear have grown into a problem of great significance. And we are convinced, in the light of this, that its theoretical analysis and practical solution, aimed at raising the stability and viability of the rear, have considerable interest, and promote a further increase in the combat readiness of the operational war.

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "On the Question of the Tasks, Organization and Planning of Military-Scientific Work" by Rear-Admiral V. Bogolepov.

This article appeared in the 1962 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1962 First Issue went to press on 29 December 1961.

Headquarters Comment: Military Thought is published by the USSR Ministry of Defense in three versions, classified RESTRICTED, SECRET, and TOP SECRET. The RESTRICTED version has been issued monthly since 1937, while the other two versions are issued irregularly. The TOP SECRET version was initiated in early 1960. By the end of 1961, 61 issues of the SECRET version had been published, 6 of them during 1961.

On the Question of the Tasks, Organization and Planning of Military-Scientific Work

by

Rear-Admiral V. Bogolepov

The thoughts presented in this article are the results of some of the author's experience in the work of scientific-research groups created during the last four years under the Commander-in-Chief of the Navy.

The great and constantly growing significance of science in our country is known. The application of science has become one of the decisive factors in the mighty growth of the productive forces of society. At the XXII Congress of the CPSU, N.S. Khrushchev stated: "The constant improvement of the forms and methods of the management of the national economy, the most rational use of internal resources and potentialities, and adherence to scientifically founded proportions in the development of the branches of the economy are taking on special significance now..." (underlined by me - V.B.)

Life itself demands of the planning and economic management of new developments a much higher order of scientific substantiation and economic calculations. Profound scientific work on the problems of developing economics and technology must precede the formulation of plans and the confirmation of economic measures. Economic and technical research must facilitate the correct performance of economic tasks.

Obviously, military-scientific work should be approached with equally high standards, because it is gradually becoming the cornerstone of Armed Forces

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

development. Military-scientific work in the broad sense of the word encompasses all research activity on military subjects. However, military-scientific work is normally considered to be only the part of this work that concerns military theory and that does not touch upon questions of armament and military equipment. In this article we shall arbitrarily call this part of general military-scientific work military-scientific operational work (including in it not only operational but also strategic and tactical questions), and we shall call the second part military-scientific technical work.

The organization of both component parts of military-scientific work is also different. Military-scientific operational work is conducted by certain faculties and in scientific groups of military academies, in military-scientific societies, and also by the scientific aktiv that is gathered around Military Thought, Naval Collection, and other military journals. During the past few years such work has also been performed in the scientific groups cited in the branches of the Armed Forces. Military-scientific technical work is also taken up in part by the majority of the faculties of academies, according to their curricula, and mainly by the numerous specialized scientific-research institutes of the various branches of the Armed Forces. Experimental-design work and, to a certain degree, the scientific-research work of industrial institutes serving the Armed Forces, are combined with their work.

In the second field of military science there is not only a huge numerical superiority of persons working directly on questions of military theory, but also significantly better organization of scientific work. Military-scientific technical work is conducted mainly in specially organized and equipped scientific establishments, such as institutes, and is fulfilled, as a rule, by harmonious scientific collectives. At the

same time, scientific work in the field of military theory is scattered among a number of establishments, is often fulfilled by persons working alone, not connected with one another, and, if it is fulfilled by collectives, the latter are often selected not on grounds of scientific qualifications, but are staffed by chance (in particular, many scientific groups in the branches of the Armed Forces have actually been selected in this way).

At a time when military-scientific technical work has, for a long time now, been carried out according to specific plans, often connected with large financial appropriations, and is usually fulfilled under rigid supervision, work in the field of military theory began to be planned only recently. It is poorly supervised and in a number of cases its quality leaves much to be desired. As an example, 2 to 4 years ago when one of the scientific groups was working on the problem of combatting ocean-sea communication routes and tried to familiarize itself with existing scientific material on these questions, it was discovered that among the several hundred pertinent monographs, dissertations, graduation theses, and articles, half of them were devoted to one single, important, but isolated topic, "Combat of Submarine and Air Forces Against Remote Enemy Communication Routes". In turn, a large part of the works in this half were compilations that were of no real value. At the same time, a number of vital questions of this combat against communication lines seemed to have dropped out of the field of view of our naval theoretical literature.

Such a situation is characteristic not only of work on this problem, but also on other problems. It can only be explained by deficiencies in planning and by a certain lack of organization in the selection of the subjects of scientific work. With all the need to give scientific personnel freedom in the selection of subjects, the overall maneuvering of scientific forces and capabilities must, first of all, ensure

research on all the essential questions with the necessary time limits.

Finally, while persons working on questions of armament and military equipment are constantly informed on the latest scientific-technical achievements in their field, since without this their work proves to be fruitless, the majority of the theoretical workers in the operational field, because of security considerations, are often not given access to documents that reflect pertinent achievements in the field of science and technology.

To summarize, with the comparatively large number of operatives and tacticians working on the theoretical front, with their quite high training and essential aptitudes*, the coefficient of the useful operation of our military-scientific network is not great: the factual results of its work are much lower than its potentialities. Lately, in connection with organizational-staff reductions, the position of operational scientific work has become even worse, not only absolutely but also relatively. These reductions have had less effect on scientific-technical work.

With any personnel reductions in the composition of the Armed Forces, military-scientific work cannot be weakened, but, just the opposite, it is necessary to broaden and deepen it in every possible way,

* Here we do not examine the situation of laboratory, experimental and the experimental-production base of our academies, and especially, scientific-research institutes. This question deserves separate discussion. It should only be said that in this field much better cooperation is required than exists now between them, especially with organs of industry.

[redacted] 1.3(a)(4)

because only in this way is it possible to compensate for the quantitative reduction of forces. This pertains especially to scientific work in the field of military theory. For, in general, it should stand at the head of the military-scientific, including scientific-technical work. Indeed, this is also demanded by the development of armament and equipment itself.

Of course, changes in the development of weapons and equipment determine changes in the development of military affairs. But, undoubtedly, military theory also exerts its own reciprocal influence on military theory. Military technology cannot develop swiftly without being oriented by military theory. The latter has to indicate paths of development to military technology, the most effective ones from the standpoint of military art. Only on this basis is it possible to develop practical scientific-technical work in the most advantageous directions.

Now, when science and technology are developing so fast, acute scientific thought must be aimed at not less than ten years ahead. Only with this condition is it possible to possess modern armament and equipment of forces at any given moment, because scientific-technical and design work, the testing of experimental models, and the creation of large and smallseries, on the average, take just ten years.

In particular, the matter of research on comparative military effectiveness stands very poorly, including the military-economic profitableness of various methods of fulfilling particular strategic, operational, and even tactical, tasks. In conditions of the use of weapons of mass destruction, and their delivery to targets by missiles, almost any one of these tasks can be performed by various methods and correspondingly with various constituents of forces and weapons, belonging to various branches of the Armed Forces.

[redacted] 1.3(a)(4)

These forces, weapons, and methods are by no means equal in value - both purely military and military-economic. But, unfortunately, such comparative investigations are mainly conducted in scientific organs of the separate branches of the forces, and this does not ensure their necessary depth and objectivity, not only as a result of "parochial favoritism" and, thus, of a biassed attitude toward the capabilities of other branches of forces, but even as a result of the aforementioned insufficient knowledge of future possibilities of their neighbors, and likewise as a result of the lack of a common methodology of comparison.

The tasks of the Armed Forces on ocean-sea axes that are quite characteristic in this respect are shown in the table that follows. On the one hand the water has already lost its former "privileged" position, when it served as the only means of communication between bodies of land separated by it. Now the most universal medium, in this respect, is the air. Even though air transport is still limited in respect to weight and dimensions of cargo, and as a result of its relative high cost, a number of tasks formerly performed only on the water and from the water, now can well be carried out outside this medium.

On the other hand the water medium represents the most diverse field of operations, both for surface, submarine, and air forces and weapons. Moreover, for submarine forces it still ensures a fairly high degree of security.

To summarize the general formulation of the question of the preferred composition, not of the "navy" or even of the "ocean-sea forces" but of the forces capable of operating on ocean-sea axes, now comes to the following.

A. To have an effect on any objectives on the water, partially under the water, and also territorial objectives located "across the water", i.e., now it is

[redacted] 1.3(a)(4)

also possible to perform the tasks cited in the table — 1a, and all of 2 and 3 — from the shore. But because , in a number of cases, these operations from the shore (especially against mobile targets) require too complex and expensive a system of target designation and guidance, it must be thoroughly examined against which specific objectives, when and under what conditions, specifically at what distances from shore, it is more advantageous to employ weapons, namely missiles, from the shore and when it is advantageous to employ them from "intermediate" carriers, i.e., first load them on special, mobile submarine, air or surface "platforms" and send them to sea (ocean), in order to move the weapons closer to the objectives.

Besides, as regards task 1a, it is necessary to note the importance of its study in this respect. Now submarines are recognized as the most promising forces for antisubmarine defense, including, above all, operations against missile-carrying submarines. Taking into consideration the very great significance of such defense for us and the huge forces required for it, maybe it is more advantageous to direct submarine construction mainly in this direction? But in some conditions our missile-carrying submarines (as the Americans themselves consider) will prove to be more advantageous than intercontinental missiles? All the more reason that the entire problem must be thoroughly analyzed as a whole.

The question of combat against communication lines, i.e., task 2 * has been studied the most. However even here there is insufficient clarity in

* See the book "Fundamentals of Employing Submarine and Air Forces Against Ocean... (several words missing) 1960.

the point that was just emphasized: with what weapons is it more advantageous to destroy enemy ports and bases - missiles from submarines or intercontinental missiles? And in conditions of nuclear warfare ports are the main objective in combat against communication lines!

The question of the optimal forces, weapons and measures for performing task 3 has been developed even less.

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

As regards task 3a, i.e. combat with aircraft carriers and missile carriers, both aircraft and submarines can and must be used for this. However, the employment of ballistic missiles from the ground against them, as well, seems to be promising and requires thorough investigation.

Task 3b, i.e. combat with missile-carrying submarines of the enemy, is especially complex and requires all-around utilization (and hence, also, all-around investigation) of the potentialities of a number of branches of the Armed Forces.

Despite the fact that the next task, i.e. 3c, antiair defense and antimissile defense, must be performed mainly by the forces and weapons of a special branch of the Armed Forces, the participation of the Navy is also useful in its investigation, because some of its potentialities in this respect, namely, the potentialities of mobile radar patrols, that are brought forward deserve attention.

Understandably, in modern conditions, task 3d, i.e. antilanding combat, requires special cooperation of the various branches of forces and corresponding research work.

B. As regards the more or less similar tasks 1b, 4a and 4b, which relate to sea transport, such short-range transport, within the limits of the possibility of our screening them with air and sea forces, are completely feasible even now. But we are now working enough on the question of the optimum forces, weapons and methods for supporting them, and the main thing is that we do not keep this question in the field of continuous attention.

If we refer to long-range transport, namely trans-oceanic, then, of course, military science must always be ready to report at the first demand of the leadership, comprehensive, clear views on the most advantageous variants of forces, weapons and methods for carrying out such transport, with detailed calculations of the time periods necessary, and the cost of creating these forces and weapons. Logically, the following thoughts should be presented here.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

IRONBARK

1.3(a)(4)

[redacted] 1.3(a)(4)

Long-range (transsea and transoceanic) transport may be carried out on the water, in the air and by special methods.

Large-scale underwater transport has poor future prospects, as a result of its high cost and vulnerability.

Surface transport is entirely feasible but requires the support of forces that are superior to those of the enemy. What kind of forces? At present, with the inadequate range of aircraft — mainly surface means. Calculations show that if we wanted to we could create such forces no earlier than 15 to 20 years from now, and this is clearly useless. In the first place, in ten years the international situation will have changed sharply. "When the Soviet Union becomes the first industrial power" —said N.S. Khrushchev at the XXII Congress — "when the socialist system is finally transformed into the decisive factor of world development, when the forces of peace multiply even more throughout the entire world, then the balance will finally be tilted in favor of the forces of peace and the barometer of the international weather will show: clear. The threat of a world war will have passed forever."

Secondly, the technical situation also changes: it will suffice for autonomous aircraft to appear, to have the significance of aircraft carriers fall off sharply.

Hence the only realistic possibility for our carrying out such transport consists of creating sufficiently autonomous, powerful aircraft— not only for the direct performance of part of the transport by air, but also for screening the other part of it —— the transport carried out by sea. And because we also need these aircraft for other purposes, all efforts should be exerted toward its creation, the more so, because of other reasons, we cannot permit the Americans to outstrip us in this field.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

IRONBARK

1.3(a)(4)

[redacted] 1.3(a)(4)

In his recent speeches President Kennedy spoke coolly about atomic aircraft. Of course, for the USA and Britain, which possess powerful aircraft carrier fleets, atomic aircraft are really unnecessary. But is not the USA simultaneously trying to confuse us with its announcements? Do not the remarks of the President remind us of the objections of the USA and Britain at the 1921-1922 Washington Conference, against submarines, which represented a clear threat to them? We cannot escape this thought.

C. In actuality the possibilities of performing task 5 have already been examined, and as regards task 6, in addition to what was said above, an important question is the creation of an amphibious fleet, which, unfortunately, we hardly concern ourselves with.

A few years ago the former Minister of Defense, Marshal of the Soviet Union Zhukov, said that since the ground forces themselves possess powerful strike weapons, they are not in need of support from the sea. This, of course, is not so. If there is no navy at sea, then some kind of seagoing forces will have to be created by the army itself, as this is done to a significant degree by the U.S.Army, even though they possess a navy. The question is only a matter of what is more advantageous.

This, in brief, is not a program of the necessary investigations of the future forces, means and methods for performing tasks that are before the Armed Forces on the oceans and seas, but the prerequisites to formulation of such a program, and then only some prerequisites, because a number of other important questions have hardly been touched upon—for example, the cooperation of forces and their support—for such an important question as the most feasible standardization of the organization and control equipment in all branches of the Armed Forces, etc..

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Incidentally, it may be said that, while already long before the Second World War the constant and "general" threat of enemy aviation forced the creation of a unified system of antiair defense, now we are even more in need of having, if possible, standard organization and equipment of the control of all the Armed Forces (including observation, communications, secure communications and computer equipment).

As was already stated, the above, as well as other important questions, must be investigated not only directly from the military, but also from the military-economic standpoint. This has almost been ignored until the present time, which explains the completely inadequate development of the methodology of military-economic calculations. For the calculations must be carried out not only for each separate task but also for "algebraic sums" of particular variants of these tasks. Therefore, it is clear that this methodology must be common for all branches of the Armed Forces, but, of course, taking into consideration the specific characteristics of each of the branches of forces in their particular sectors.

"Freedom is the basic necessity." Under the existing situation, complete freedom in selecting the particular forces and weapons which are really better is lacking in a number of cases. It is lacking not only within one or another branch of the Armed Forces, but on the scale of the Armed Forces as a whole. It is already unnecessary to say that such a situation inevitably leads to the need for "impulsive" decisions, opens a broad field for all kinds of irresponsible statements, unnecessary friction, etc..

Naturally the correct solution to this entire, particularly important problem consists of the organization of timely, close, joint, creative scientific work of military theoreticians and engineers. The

question is only how to organize this work correctly, including the correct control and planning of it.

Also, overall considerations and security requirements have forced and are forcing the differentiation of this entire activity above all by the degrees of its concentration and significance. But it is important that in each of its "stages", the abovementioned creative operational-tactical collaboration should be retained. How is it best to organize it?

From the above it is clear that as the paramount scientific organ, it also works directly, plans the work of the "scientific periphery", may only exist at the level of the Ministry of Defense, most likely in the composition of the General Staff or of its Chief Operations Directorate. Only in this way is it possible to ensure complex purposefulness (perspective) and coordination of the development of the individual branches of the Armed Forces and thus, of the Armed Forces as a whole, along with the requisite competence of this organ, and the necessary security of its work.

Occupying itself only with future problems, i.e., being completely separated from current operational planning, this organ, incorporating several tens of the most qualified scientific workers and engineer-specialists on basic types of weapons and equipment*, must work on three basic problems:

— on scientific research into the most promising ways (variants) for performing the main strategic tasks that stand before the Armed Forces;

* Since such a technical organ already exists in the composition of the General Staff in the form of the Scientific-Technical Committee (NTK), maybe it would be best to simply reconstruct this NTK appropriately. Another variant could be the appropriate organization of military-scientific work of the General Staff Academy.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

— on the promising all-around system of armament that ensues therefrom, and equally on the optimal sequence of its creation;

— on the operational-tactical principles for the subsequent development of assignments for the main models of weapons and military equipment that ensue from this system of armaments.

Of course, the small staff of this central scientific organ will be able to handle the huge volume of tasks listed only under the following conditions:

— if its foundation is the work of the "scientific periphery" i.e., other scientific organs such as of the ministry as a whole, as well as of the branches of the Armed Forces;

— if at the same time it carefully follows the achievements of the general non-military sciences capable of having some military significance, and for this its representatives will enter into the top scientific organs of the country that have military interest, in the capacity of observers of their own arm;

— if it does not start to disperse the attention given to insignificant things, both in its own theoretical-research work and in its methodological management of the work of the other scientific organs of the ministry.

In order to observe these conditions it is necessary to deal only with the scientific organs (institutes) of the ministry, that work directly with it, and with the appropriate scientific management organs of the branches of forces. In turn, the latter organs must manage all the scientific establishments of their own branch of forces.

As regards the peripheral network of scientific organs of the Ministry as a whole, and of the branches of forces,

[redacted] 1.3(a)(4)

i.e., academies and scientific-research institutes, in each case their scientific work should be directed toward the accomplishment of an immediate primary task of a particular faculty or institute — operational-tactical or technical. The cooperation of military theory with research in the field of weapons and equipment should fundamentally be ensured just as is done now. In the academies it may be founded on the joint work of related faculties; in institutes — on the existence in each one of them of an overall tactical department parallel with the specialized departments, etc.. The appropriate staffing of the scientific-technical councils of institutes and academic councils of academies must play a definite role.

This reveals the double subordination of scientific organs, that actually exists even now anyway: in all respects — to its immediate command (institutes — to chiefs of the appropriate directorates; faculties — to chiefs of academies, etc.);and in a special respect, more precisely in a scientific-methodological respect — to the scientific organ of the senior command. In the final analysis the faculties of academies and institutes in this special respect must be directed by the scientific management organs of the main staffs of the branches of forces, and these organs — to the management of the General Staff scientific organ. The central scientific establishments of the Ministry that do not enter into the composition of any central directorates must also be directly subordinate to the latter.

As at present, the actual plans of their work — long-range and annual — must be made up by each scientific organ, being guided by the directions of its command and senior scientific organ. In order to decrease inconveniences connected with double subordination, the senior scientific organs must give basic directions to the junior ones only through the chain of command, for example, to scientific organs of the main staffs — in the name of

[redacted] 1.3(a)(4)

the General Staff. In order to avoid delay in the planning of these instructions from the General Staff to the main staffs, they must obviously arrive not later than 1 September, and from the main staffs to the directorates, not later than 1 October of each year.

In all plans not less than a 20 percent reserve must remain for performing "specialized" ("fakultativnyy") tasks that were not envisaged earlier. With the goal of improving planning, to insure first of all the essential subjects and to eliminate the search for the most important questions, when "time limits are already being felt", each planning stage must have and must constantly maintain at a current level, thought out, systematic lists of the most important subjects for research work in the basic sectors under their jurisdiction.

* * *

Science constantly enters into our life and into military affairs more and more. The purposeful "maneuvering" of scientific forces and capabilities to point them toward the performance of the main tasks that facilitate progress has vast significance that has already been recognized. In this respect, the newly formed State Committee of the Council of Ministers USSR for the Coordination of Scientific-Research Work is the main aid to the leadership of the country.

There is no doubt that the management of the entire system of military scientific-research work must be organized in a centralized way something like this, with differences arising from the specific characteristics of the Armed Forces. But successful overall treatment of the paramount military-scientific problems can be ensured only by the presence in the system of this work of a corresponding competent top military-scientific organ.

SUBJECT : MILITARY THOUGHT (TOP SECRET): "Problems in the Development of Antiair Defense of the Ground Troops and Ways to Resolve Them", by Colonel V. Zemskov

DATE OF INFO : December 1961

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "Problems in the Development of Antiair Defense of the Ground Troops and Ways to Resolve Them", by Colonel V. Zemskov.

This article appeared in the 1962 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1962 First Issue went to press on 29 December 1961.

Headquarters Comment: Military Thought is published by the USSR Ministry of Defense in three versions, classified RESTRICTED, SECRET, and TOP SECRET. The RESTRICTED version has been issued monthly since 1937, while the other two versions are issued irregularly. The TOP SECRET version was initiated in early 1960. By the end of 1961, 61 issues of the SECRET version had been published, 6 of them during 1961.

Problems in the Development of Antiair Defense of the Ground Troops and Ways to Resolve Them*

by

Colonel V. Zemskov

Under modern conditions, the role of antiair defense has grown so much that the course and outcome of ground troop operations depend to a large extent on its effectiveness. This is conditioned by the fact that our probable enemies consider a nuclear offensive, in which the leading role is assigned to missiles and aircraft, to be the main substance of the first strategic operation of the united Armed Forces of NATO in the initial period of a war. The goal of such an offensive is to achieve, in a short period of time, nuclear superiority, supremacy in the air and seizure of the strategic initiative from the very start of the war. Its scope can be judged from the experience of the "FALLEX-60" NATO maneuvers where, during three calendar days of the nuclear offensive, 1660 nuclear strikes were conditionally delivered, and up to 5000 aircraft, and also a large number of cruise missiles, "Thor" ballistic missile launchers, URS (upravlyayemyy reaktivnyy snaryad - guided missiles) and NURS (neupravlyayemyy reaktivnyy snaryad - free rockets) of the ground troops participated. Effective combat with this large number of carriers of nuclear charges represents one of the most important tasks of the ground troops in conducting operations during the entire war.

In the light of this, it should be noted that the work being reviewed has great theoretical and practical significance. Its authors, examining the most important problems of ground troop PVO, took a basically new tenet as the basis of

*Problems in the Development of Antiair Defense of Ground Troops and Ways to Resolve Them. Military Publishing House, 1960, 240 pages and 4 inserts.

IRONBARK

[redacted] 1.3(a)(4)

their investigation, which consists of the fact that antiair defense has now outgrown the framework of support and is one of the main component parts of the substance of troop combat operations, directed toward the destruction in the air of the enemy's basic carriers of nuclear weapons--his aircraft and missiles.

Proceeding from this concept, in the first chapter the influence of modern troop combat operations on the organization of antiair defense is correctly brought to light, and the basic requirements for it, resulting from the peculiarities of the operations of the air enemy under the conditions of a nuclear/missile war and the employment of new attack weapons by him, are validly formulated. It is stressed that the antiair defense weapons of the ground troops, by their active operations to destroy enemy aircraft and missiles, actually participate in the struggle for nuclear superiority over the enemy.

The process of changing weapons of air attack has unavoidably required a sound determination of the line of further development of the antiair defense weapons of the ground troops. This most important question is examined in the second chapter.

For combatting operational-tactical ballistic missiles, it is proposed to have special weapons—antimissile missiles, and for destroying high-speed piloted aircraft and cruise missiles at all altitudes, antiaircraft guided missiles of three types: --long-range (ZUR-D) (zenitnaya upravlyayemaya raketa-dalnyaya),--intermediate and short range (ZUR-S) (zenitnaya upravlyayemaya raketa - srednyaya) and (ZUR-M) (zenitnaya upravlyayemaya raketa - malaya). These types of missiles must comprise the basis of the antiair defense of ground troops. Close action antiaircraft guided missiles (ZUR-B) (zenitnaya upravlyayemaya raketa - blizhnyaya) manual and mounted (ruchnaya i stankovaya) are recommended as the basic means of combat with low-flying,

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

mainly low-speed, aerial targets.

Concerning small-caliber antiaircraft artillery and fighter aviation, in the work it is pointed out that so far they have not yet lost their significance, but they will be ousted by antiaircraft guided missiles, as the weapons having the greatest future promise. It is possible to agree with this only in regard to antiaircraft artillery. Nevertheless, the authors persistently adhere to the idea that there is a need to improve antiaircraft artillery, even to create new models of multiple small-caliber antiaircraft artillery with autonomous radar sights. The question arises, is there any sense in expending considerable scientific-technical and productive efforts to create new models of these weapons? Isn't it better to work out more quickly, and introduce into the troops, the most effective antiaircraft guided missiles of all types?

The conclusions of the authors concerning fighter aircraft, in our opinion, are premature and not quite correct. Modern fighter aircraft, armed with "air-to-air" class missiles, are, at the present time, one of the basic means of antiair defense. In the future their significance and proportion in the overall system of antiair defense will undoubtedly decrease. However, it is impossible to fully replace them with antiaircraft missiles, and is hardly advisable, because both fighter aircraft and antiaircraft missiles have their merits and deficiencies, which can be compensated, and, consequently, continuous reliable antiair defense may be achieved only by joint use of all the forces and weapons of the PVO.

The tactical-technical requirements for all the weapons of ground troop antiair defense are, in our opinion, basically determined correctly in the book. But the proposed combat altitude of long-range and medium-range antiaircraft guided missiles is the same - from 2 to 4 to 25 to 30 km. It seems to us that these

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

figures are only applicable for medium-range missiles. For long-range antiaircraft guided missiles it is necessary to increase them to 35 to 40 km. The ceiling of enemy aircraft operations now has already reached 25 to 30 km, and for automatic balloons of strategic designation--30 to 35 km. And, undoubtedly, in the near future the flight altitude of these weapons will increase.

In order to conduct modern operations, the average tempo of which reaches 100 km per calendar day, it is necessary to have highly maneuverable PVO weapons. The existing (S-75) missile complexes are not maneuverable enough because of the low mobility, not only of the launching mounts, but mainly of the missile guidance stations. However, the authors have not examined this question and have not formulated the scientifically based tactical-technical requirements for the missile guidance and target allocating stations which must be included in future antiaircraft missile complexes.

In examining the fundamentals of the operational-tactical employment of troop antiair defense weapons and the most acceptable ways to resolve the problems of firing against aerial targets (Chapter Three), in the beginning the authors give brief recommendations for employing antimissile weapons that are not yet available in the armament of the troops. Despite the fact that these recommendations are presented in a theoretical way, they may be examined as the basis for the practical combat employment of those antimissile missiles that will enter the armament.

In the book being reviewed, the bases for employing antiaircraft missile weapons are presented in a fairly detailed manner, based on theoretical research and a collation of accumulated experience. It is stressed that the employment of long-range and intermediate-range antiaircraft guided missiles, because they are a means of zonal cover, must have a clearly expressed operational nature. Short-range antiaircraft guided

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

missiles may be used for both zonal and direct covering of troops and objectives. Therefore their grouping must have an operational-tactical or only a tactical nature. Recommendations on the grouping of missile units are also argued with adequate conviction and may be incorporated into the basis of practical activity; in creating them it is necessary to observe the principle of deep echelonment, including the larger part of them in the first, most powerful, echelon of the PVO.

In modern operations, observance of the principle of continuity in covering troops and objectives attains exceptionally great significance. In investigating this question special attention should be given to the organization of coordination of antiaircraft guided missiles with fighter aviation in order to insure true continuity of troop PVO in an offensive and the organization of the employment of antiaircraft missile units during combat operations conducted at a tempo of more than 4 km per hour.

However, the possibility of further increasing the tempo of an offensive is not sufficiently considered in the work. Only one version of displacement is given and it is stressed that continuity of troop cover will be disrupted with an average offensive tempo of more than 4 km per hour. Consequently, during pursuit, when troops will be moving at higher tempos, this task cannot be performed at all. However, the organization of coordination of antiaircraft guided missiles with fighter aviation, with the goal of insuring continuity of troop cover during an offensive operation, has not been examined at all,

Under modern conditions, in view of the fact that the most varied, including high-speed, weapons of aerial attack exist, the problem of organizing coordination between antiaircraft guided missiles and fighter aviation has become considerably more complicated. On the whole, in the work the basic propositions are correctly formulated on these three types of coordination: --distributing

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

efforts by zones; in one zone, and by time. The most complex, and at the same time the most effective in practice, is the organization of coordination by means of distributing efforts in one zone. It should be expected that this very question will be given the greatest attention. Unfortunately, very few specific practical recommendations on it are given.

The problem of organizing radio countermeasures against the air enemy in ground troop operations is fairly new. Nevertheless the authors were able to formulate the basic tasks of radio countermeasures fairly accurately and correctly and point out the general scheme for the utilization and the principles for organizing the combat operations of these means. However, the recommendations made require comprehensive practical checking. On the whole it is essential to continue constantly and persistently to work on this problem.

Questions of methods for determining the required quantity of the basic active weapons of antiair defense are thoroughly brought to light in the work. However, the collective authorship proceeded from the potential scale and nature of the operations of the enemy's weapons of aerial attack according to data for only up to the beginning of 1960. In a problematical work the nature of possible changes in the development of these weapons should have been pointed out in general terms. The reader who will use the data on the quantitative and qualitative composition of the aviation-missile grouping of the probable enemy must keep in mind that even now it has already undergone substantial changes. This is especially applicable as far as the missile weapons are concerned. Besides, it should be taken into consideration that since 1960 the NATO Command has begun widescale adoption of carrier-borne aircraft, which was not so in the past, and also "Thor" and "Polaris" missiles, to participate in a nuclear offensive and to support combat operations of the ground troops.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

In principle, the method for determining the required number of active PVO weapons for front troops, proposed by the authors, is acceptable. But a slightly overestimated version of the composition of the front troops was used as the basis of the calculation. Experience from operational-strategic exercises of the last few years shows that the composition of the front troops usually includes only 17 to 20 up to 25 to 26 combined-arms divisions, and not 26 to 35, as indicated on page 89. And in the future, in our opinion, the composition of the front, as the number of nuclear weapons allocated for an operation increases, can only decrease somewhat, but not increase. Besides, in the given version of the calculation, it is not pointed out which operation is being carried out by the front, defensive or offensive. Consequently, some abstract version of the amount of active PVO weapons required by the front troops is proposed. This would be justified only if the authors considered that such a factor as the nature of the operations of the troops being covered does not influence this. But, on page 80, they themselves point out that "the nature of the use of the troops being covered in an operation and a battle" should be taken into consideration. Moreover, on pages 208 and 213 (tables 17 and 18), two more versions of the composition of the active PVO weapons of the front are given, but here separately for offensive and defensive operations.

On the whole, despite the fact that this question is given a great deal of attention, it is still stated in a contradictory manner and without adequate bases. In our opinion, when determining the required quantity of active PVO weapons, it is most correct first of all to take into consideration the nature and the proposed scope of the front operation, and in all cases to be guided by this, together with consideration of other factors.

Up until recently, many varying opinions and views existed on questions of the control of PVO troops and their coordination, both in theory and in practice.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

In our opinion, the authors, on the basis of a thorough analysis of theoretical research and accumulated experience in the troops, were able, on the whole, to make completely correct conclusions and practical recommendations (Chapter Four).

It is stressed completely fairly that under modern conditions the front must carry out only operational control of all the PVO weapons of the front. The functions of tactical control should be given to the army level. In connection with this, in the front and army, it is proposed to have a PVO troop staff or a control organ that would be capable of insuring firm and continuous direction of all PVO weapons during an operation. But having, on the whole, made a correct conclusion concerning the inadvisability of carrying out tactical functions at the front level, the authors for some reason recommend that the chief of the PVO troops of the front should have part of the PVO weapons under his direct control, while failing to point out the purpose for which these means are necessary, as well as specifically how and by whom their fire will be controlled.

Reliable cover from nuclear strikes of the main rear area objectives, especially missile-technical units, and also of transportation centers, has great significance. The authors correctly stress that with the modern spatial scope of operations it is impossible successfully to perform this task without creating control organs for PVO weapons within the front rear area headquarters.

For effective control of modern PVO weapons, the authors of the reviewed book propose the creation of a special autonomous system of communications. In addition, the need to use the channels of the combined-arms communications system for the control of PVO troops of the front (army) is pointed out. At the given stage of the development of communications equipment, this, for the time being, is the most correct resolution of the above problem.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

In the work a great deal of attention is given to an examination of the problem of comprehensive automation of the processes for controlling active PVO weapons. It is stressed that when solving this problem the required speed for transmitting data and commands, maximum centralization of the control of the basic active PVO means, and correct organization of coordination among them must be insured. The rapid development of aerial attack and PVO weapons already requires an immediate practical solution of this problem. But having resolved it in the shortest possible time, it will be difficult to count on the successful fulfilment of the tasks that face the PVO troops. The recommendations developed by the authors on this question, taking into consideration projected tendencies in the development of communications and control equipment and prospects of domestic science and technology, can, in our opinion, also be incorporated into the basis for resolving the problem of the comprehensive automation of the processes of controlling PVO weapons.

Support of the combat operations of the PVO troops of the ground troops is examined in a special fifth chapter. In this, special stress is laid on radar support.

In modern operations, success in the antiair defense of troops depends, to a great degree, on the timely and complete receipt of necessary intelligence and target designation data by all the active PVO weapons simultaneously. Having analyzed the capabilities of the existing system of radar support for PVO weapons of the front and army, the authors have come to the correct conclusion—that it is not only not capable of providing all the active PVO weapons with data simultaneously, but is not even capable of providing each of them singly (page 148).

The proposals of the authors on radar support are basically fully acceptable. However, for some reason,

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

the work does not take into consideration those means of reconnaissance and target designation that the antiaircraft missile large units and units have at their disposal. At the present time, and in the near future, they should be examined as a very substantial reserve of radar equipment in the hands of the chief of the PVO troops of the front (army). The indicated equipment can play a very important part in case operating radar posts, in those areas where combat formations of antiaircraft missile units and large units are deployed, are put out of commission. It seems to us that this question deserves investigation and practical verification in the troops.

In the reviewed work the authors devote a great deal of attention to providing PVO troops with missiles and, in our opinion, came to the correct conclusion, that it is impossible precisely to plan the expenditure of missiles by days of an operation, because it depends on the intensity of the air enemy's operations. And this factor, as is known, cannot be predicted accurately in advance. However, when presenting practical recommendations, the authors depart from this conclusion and still propose planning the expenditure of missiles released for the front by days of the operation, and even hold to the tentatively planned expenditure of missiles by days of the operation for the front. It seems to us that the authors are acting incorrectly in artificially limiting the expenditure of antiaircraft missiles and antimissile missiles. Obviously, it will be limited mainly by technical capabilities. If there is still a need to plan the expenditure of missiles by days of the operation, then it is more advisable to take the technical capabilities for assembling, equipping and delivering the missiles to fire subunits and units as the basis of the plan, taking into consideration the extremely tentative nature of the air enemy's operations.

Effectiveness in the operations of PVO weapons, to a large extent, depends on their rapid and high

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

quality engineer support. And we fully support the authors, who write about the urgent need to have organic engineer subunits, equipped with modern highly efficient and portable equipment, in the PVO troops of the ground troops.

In the sixth chapter the future organizational structure of the PVO troops of the ground troops is examined. Several versions of how large units, units and subunits should be organized are proposed. On the whole, the recommendations have many positive features, but they require checking in practice. Thus, according to the opinion of the authors, in the tank and motorized-rifle division it is more advisable to have a regiment of close action antiaircraft guided missiles than a regiment of ZUR-M. According to our deep conviction, both divisions must have antiaircraft missile regiments with short-range missiles composed of 3 to 4 fire units, and in the motorized-rifle and tank regiment there must be a battery of mounted close action antiaircraft guided missiles composed of 3 to 4 mounts. We base this on the fact that in modern operations, the operations of large units and units on separate axes and in broader zones will be most characteristic. This will require the large units to have great independence in reliably covering troops from strikes by the air enemy. In addition, it is also necessary to take into consideration the fact that motorized-rifle and tank large units and units, having ground missiles, tanks, and artillery in their composition, have great fire and striking power, and will be the most important objectives for a strike by the air enemy. For this reason, they must be reliably and continuously covered during the entire operation, not only at low, but also at medium, altitudes, which can be accomplished more simply and reliably when there are both close action antiaircraft missiles and ZUR-M in the composition of the division.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

On the whole, the proposed organization of a brigade of medium- and short-range antiaircraft guided missiles corresponds to modern requirements, but even the brigade, in our opinion, must have no less than three regiments or battalions (with three fire units in each) in its composition. By having brigades composed of three regiments (battalions), it will be possible to achieve continuity in covering troops during an offensive conducted at an average tempo of 6 km per hour.

In the last chapter the fundamentals of the antiair defense of troops in offensive and in defensive front (army) operations of the initial period of a war are set forth. Under these conditions, the PVO of the troops and rear area objectives of deploying fronts will be carried out only with those weapons that are at the disposal of the troops of the first strategic echelon, i.e., formations and large units of the border military districts and groups of forces. In the reviewed work, the requirement that the antiaircraft missile units, fighter aviation and radio countermeasure means existing in groups of forces and in border military districts, must be at full strength, deployed, and be in constant combat readiness to conduct active combat with enemy weapons of aerial attack, is correctly formulated. It should be stressed that this requirement has an extremely important significance when the aggressor is preparing for a surprise nuclear attack. Experience from the past war conclusively showed that the success of the attacking side was usually explained not only by the factor of surprise, but also by the incomplete combat readiness of the armed forces.

In conclusion, it is essential to stress that all the deficiencies noted by us are of a specific nature, and cannot lower, as a whole, a highly positive evaluation of the work. The reviewed book is the first one on the given subject in the postwar period. The authors deserve great credit for being able to create

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

a really problematical and perceptive work. It does not reiterate principles that are common knowledge, but creatively, on the basis of an analysis of the modern requirements of operational art and scientific-technical capabilities, trends, probable paths of development, and solutions to the vitally important problems of the PVO of the ground troops, are brought to light, and practical, acceptable recommendations are given. The work examined by us may be adopted as the basis for a practical resolution of the basic problems of PVO of the ground troops, not only for the present time but also for the near future.

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "A Front Offensive Operation Conducted Under the Conditions of the Initial Period of a Nuclear/Missile War", written by Colonel-General G. Khetagurov.

This article appeared in the 1960 Second Issue of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET by the Soviets and is issued irregularly. It is distributed only within the Ministry of Defense down to the level of Army Commander.

A Front Offensive Operation Conducted Under the Conditions of the Initial Period of a Nuclear/Missile War

by Colonel-General G. Khetagurov

The power of the armament of modern armies and the probable radius and force of the destructive effect of new means of combat have now reached such a level that the roles of many of the concepts and requirements of the military art which were established previously are completely or partially disappearing. Indeed, the necessity of reviewing a series of obsolete beliefs and views and of taking an essentially new approach to the solution of questions of the operational and combat employment of troops is arising. In connection with the birth and rapid development of such a new type of armed forces as missile troops, new laws are being established in military affairs and the nature and substance of the interdependence existing between strategy, the operational art and tactics are being changed.

In contrast to previous wars, when the fate of the operation was decided principally on the field of battle and strategy basically crowned the efforts of tactics and the operational art, now the operational art and tactics very often will begin with the exploitation of the results of strategy or, stated better, with the exploitation of results of a strike by strategic weapons to complete the success of such a strike. Strategy will now operate not only with mass armies but also, directly with the use of large units of strategic missiles whose employment will have decisive influence on the progress and outcome of separate operations, as well as on the armed combat as a whole.

This does not mean, however, that the missile troops can independently decide all, or even a large portion, of the war's strategic missions. As indicated by the Minister of Defense of the USSR, Marshal of the Soviet Union R. Ya. Malinovskiy, in contemporary conditions, just as previously, the successful conduct of combat activities is possible only on the basis of the coordinated use of all the types of armed forces and all means of combat. Mass employment of strategic and operational missiles

[redacted]

1.3(a)(4

[redacted]

1.3(a)(4

[redacted]

1.3(a)(4)

with nuclear charges may sharply reduce the time of attainment of strategic goals of the war, will permit the infliction of crushing destruction on the enemy in a short time, and alter the forms and methods of the conduct of an operation. But it will not in any way reduce the role of man in warfare. Man has been and will remain the principal factor in the conduct of armed combat.

It is erroneous to think that a future war will actually become a kind of "nuclear/missile duel". To the same extent, it is incorrect to believe that the operations of the ground troops will lose their significance and that their missions will be limited to the overcoming of the unorganized resistance of the remnants of the enemy's troops and to the occupation of his territory.

The experience of many exercises testifies that even with the complete destruction of the majority of the industrial areas, the elimination of the most important transportation centers from use and the destruction of the most important air and missile bases, the enemy in many cases preserves the capability not only for resistance but also for the delivery of powerful strikes, frequently restores the combat effectiveness of groupings of his armed forces, and often attempts to seize the operational initiative. His complete and final destruction in the theater of military operations, under any scale of use of nuclear/missile weapons by both sides, is achieved as a rule only as a result of very intense combat, after the capture by ground and airborne troops of vitally important areas of territory, of centers of nuclear/missile weapons production, of the main airfield network, and also of the majority of the siting areas of the enemy's operational and operational-strategic missiles.

Fulfilment of the stated missions, as a rule, requires the execution of a series of successive front operations with the utilization of a very significant quantity of troops and weapons, including troops from border military districts.

In his article[1] Colonel-General Gastilovich, along with many absolutely correct conclusions, expressed the

1 Special Collection of Articles of the Journal "Military Thought", First Issue 1960.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

assumption that in view of the expected results of the use of strategic nuclear/missile weapons for the completion of enemy destruction in the European theaters of combat operations in modern conditions, 20 to 25 divisions in all are sufficient for the composition of the first strategic echelon, but taking into account the replacement of probable losses - 30 to 40 divisions. Furthermore, in his opinion, the above-mentioned forces can meet the main resistance only in the border zone of a depth of several tens of kilometers, after which the troops will have tasks connected chiefly with the overcoming of radioactive-contaminated zones and the occupation of the territory of hostile nations. Thus, active combat operations of the ground troops, in General Gastilovich's conception, are reduced in fact to one border engagement with a subsequent swift advance by large units without serious enemy resistance.

We believe that in spite of the enormous power of strategic nuclear/missile weapons, there still are insufficient foundations for such a conclusion. This permits the well-known underestimation of the enemy, and the countermeasures conducted by him, and does not consider the actual composition and disposition of NATO armed forces in the Western theater of combat operations (TVD) or the specific conditions of the execution of nuclear/missile strikes within the theater boundaries (even though connected with the prevailing direction of the winds).

In fact, if we are to believe that after the first nuclear/missile attack, our troops, located directly in the TVD in a depth up to 1,000 kilometers, will be able to preserve up to 2/3 of their forces, why then is the same possibility excluded with respect to the enemy? Why is the probability of the formation of new troop contingents and the transfer to the TVD of strong reserves, including reserves from the USA, Spain, and Algeria, completely discounted? Is it realistic to pose a question about the possibility of absolute disruption of these measures? Why is the probability of active operations on the part of a series of enemy groupings ignored; and why is it that, from the first days of the war, we contemplate only the complete withdrawal of his forces originally deployed in the border zone? Finally, what foundations are there to

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

assume that, after the first front operations, the enemy will practically refuse to fight and that the advancing troops will have only to occupy his territory?

The experience of exercises does not confirm this. On the contrary, it shows in the majority of cases that with the conclusion of the first front operations armed combat in the TVD not only does not cease but is capable of assuming an even sharper character. The communication lines of our troops are being stretched out. The reserves fall behind. At that very time, the enemy, profiting from the great vulnerability of the crossings of our water boundaries and also from his more developed transportation system, can bring up fresh forces from the depth more rapidly and can establish new groupings and activate the use of his nuclear/missile means in a shorter period of time. As a result, a very serious situation can be created in a number of directions. It is also characteristic that at this moment, as a rule, new operational axes are opened up before the advancing troops, so that new strategic missions arise which require the introduction of additional forces and equipment.

In General Gastilovich's opinion, the 30 to 40 div divisions which began the operation must carry on the advance up to the ultimate limits of the theater. But what remains of them at the moment of completion of the immediate strategic mission? According to calculated data, verified by us in a number of exercises, on the 9th or 10th day of a war, the combat strength of up to 2/3 of the large units included in the composition of the first operational echelon of the front was generally already reduced by up to 30 to 35 percent of its original composition and furthermore, that up to 50 percent of the personnel remaining in action had to be hospitalized or evacuated to the rear because of their having received large doses of radiation.

Under such conditions it is clear that if an immediate buildup of strength from the depth is not carried out, the operation can abate and the success attained come to naught.

It is also indubitable that in the course of the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

initial period of a war large engagements will inevitably take place not only in the border zone but also further on actually throughout the entire extent of the front operations, because no matter how powerful the first nuclear/missile strikes, not all targets and all groupings of the enemy can be destroyed by them. The complete radioactive contamination of absolutely all enemy occupied territory of the TVD cannot be ensured for a prolonged time. According to the nature of the actual meteorological conditions, this is unlikely, and indeed, obviously inexpedient. Therefore, during the initial period of a war, the troops must not orient themselves for a march, but for intensive combat operations in the various areas, and moreover, not only in gaps, but also directly in the zones of high radioactive contamination.

In light of such conditions, we think that the composition of forces as defined by General Gastilovich for the fulfilment of the most immediate strategic missions will clearly be inadequate. One must proceed from the necessity of deploying a front not in the TVD, but on each of the strategic axes, incorporating not less than 3 to 5 combined-arms and tank armies in its composition, depending upon the operational scope, and also a number of separate divisions. Moreover, it is necessary to assume that in some cases the resolution of the most immediate strategic tasks might require, even during the course of the initial period of a war, an additional deployment of new armies and even fronts in the theater of military operations, not for the occupation of enemy territory, but for the conduct of active combat operations.

The specific means and forms of conduct of front offensive operations undertaken on various strategic axes during the initial period of a nuclear/missile war, will depend upon the characteristics of these axes, and the general strategic situation, but mainly upon the number and nature of the strategic nuclear/missile strikes carried out by the General Headquarters of the Supreme High Command (Stavka VGK) in the theater of military operations. It may be assumed that prior to and during the course of the first front operation, several massive strategic nuclear/missile strikes will be carried out in the axis of the offensive of each front and will be tied into one another by the general strategic plan

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

but distinguished from one another by assigned mission and by the areas of territory within whose limits the main body of nuclear/missile ammunition will be employed. The first of these strikes, usually a counterstrike, will be the most powerful. It will be conducted simultaneously in the entire strategic depth with the aim of eliminating individual states with limited territory from the war and also with the aim of inflicting within a short time by the main groupings of the armed forces, such losses as would permit the rapid seizure of the strategic initiative in the very beginning of the war.

In subsequent massive strategic nuclear/missile strikes, the main efforts of the missile troops can concentrate either on the fulfilment of analogous missions but with destruction of other less important or surviving targets or switch to the destruction, primarily of economic centers and areas, ports and transportation centers, with a view to the rapid annihilation of the enemy's military - economic potential and the disruption of his mobilization measures and strategic transport.

Of course such a sequence in the implementation of strikes is not the only one possible. It should be examined only as one of a large number of the most probable forms of the use of strategic nuclear/missile weapons. Quite varied forms of massive strategic nuclear/missile strikes can be employed in a specific situation in a TVD. It is not ruled out, for example, that in every one of them all of the tasks mentioned above will be resolved simultaneously rather than consecutively, in which case the sequence of the neutralization of targets for every group of tasks will be determined in accordance with the degree of their importance and the general concept of the strategic operation.

The main and decisive role in the execution of massive strategic nuclear/missile strikes will undoubtedly, belong to the strategic missile large units directly subordinate to the Stavka VGK. However, in a number of cases, both for the initial and successive strikes, it is also possible to include the missile weapons of the fronts for the fulfilment of separate tasks in a zone

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

up to 300 to 500 kilometers from the border. In organizing their utilization, the Stavka VGK, apparently, will indicate to the front troop commander:

- the areas for carrying out nuclear/missile strikes to be accomplished by strategic weapons in the front zone of operations and capable of rendering direct influence on the development of the initial front offensive operation;

- the time and composition of front missile weapons included in the participation in the counterstrike and of subsequent massive strategic nuclear/missile strikes;

- the borders of the sectors established for the use of missile weapons of fronts;

- the tasks of front missile weapons to be fulfilled in the interests of the entire strategic operation, with instructions regarding the targets to be destroyed, their coordinates, and the time of destruction;

- the direction, zone, or the area within the borders of neighboring fronts in which maneuvers by nuclear/missile strikes must be prepared.

On the basis of this, the front troop commander must make a specific decision with regard to the destruction of all targets assigned to him or selected independently, including: establish the number of nuclear/missile strikes conducted by front and army weapons; the expenditure of nuclear ammunition utilized; plan the sequence and order of destruction of various targets, the yield and types of nuclear bursts, the coordinates of their epicenters, the means of delivery of nuclear weapons to the target, the time of their readiness, etc.

The execution of powerful strategic nuclear/missile strikes in the TVD will raise sharply the capabilities of the fronts, will lead to a further increase of the scope of front operations, and at the same time will seriously affect their makeup.

When planning an operation, the front troop commander

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

must carefully calculate the influence which the strategic nuclear/missile strikes may have on the operations of troops under his command, must estimate the probable level of destruction of various enemy groupings and targets, envisage when and which areas will become zones of high level radioactive contamination as a result of surface nuclear bursts and how these will reflect on fulfilment of the tasks assigned to the front.

Only after this can correct conclusions be drawn regarding the expedient organization of the operation, the most advantageous grouping of forces and weapons, the direction of the main strike, the order of use of our missile and nuclear weapons, and also, regarding all other questions of operational planning.

As a whole, the concept of a front offensive operation undertaken in the initial period of a nuclear/missile war must, in our opinion, reflect the following basic points in all cases:

1. The order of participation of front nuclear/missile weapons in the counterstrike and of subsequent massive strategic nuclear/missile strikes organized by the Stavka VGK in the theater of military operations.

2. The method of exploitation by ground and airborne troops of the results of nuclear strikes carried out by large units of strategic missiles and missiles of medium range.

3. The method of destruction of the deploying or deployed strike groupings of enemy troops by combined operations of operational and organic (voyskovaya) missiles, ground troops, aviation, and airborne troops.

4. The nature of the active cover of secondary axes by a minimum of forces in conjunction with a wide maneuver of nuclear/missile weapons depending on the possible operations of the enemy.

Of the aforementioned, it is especially worthwhile to examine the measures ensuring the opportune exploitation by a front of the results of strategic nuclear/missile

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

strikes. We imagine that the aforementioned requirement will be achieved first of all by means of a swift breakthrough by front tank groupings into points or areas neutralized by strategic nuclear/missile strikes, with the aim of seizing these areas before the enemy liquidates the results of the assault; by the development of vigorous offensive operations at the moment when a large portion of the enemy operational-tactical weapons for nuclear attack will be neutralized or put out of action; by the utilization of zones of contamination created for the disruption of an enemy maneuver, blockading his groupings from the flanks, and for the economy of friendly forces on axes where because of an unfavorable radiation situation the operations of ground troops will prove to be impossible.

As regards other elements of the concept connected with the organization of destruction of the groupings of missile units, ground troops, and aviation deployed by the enemy on various axes in the front zone, it is our opinion that in all situations they must contain the idea, firstly, of surprise nuclear/missile neutralization of the most important groupings by front, army, and organic missiles at the most favorable moment, and secondly, the immediate exploitation of results achieved by combined-arms and tank armies by inflicting swift strikes from the march on those axes where the enemy does not expect it and where, as a result of the massive use of nuclear missiles, he is weakened to the greatest degree. In short, the front troop commander must determine when, where, and in what way the decisive destruction of the enemy will be carried out by various groupings with the assistance of front and army nuclear missiles and then --- what form of operational maneuver by the ground troops can be employed in order to finally destroy and finish off his troops, annihilate or capture an airfield, launching installations, and missile bases, thus ensuring the complete fulfilment of the assigned tasks of the operation.

It can be assumed that four groups of strikes, each different in character, will be delivered in the direction of the operations of the front troops:

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

- strategic nuclear/missile strikes carried out in accordance with the policy of the Stavka VGK for the destruction of the enemy in the theater as a whole;

- nuclear strikes executed by strategic weapons at the request and in the interests of the front;

- nuclear strikes by front weapons carried out according to the Stavka plan for the fulfilment of individual missions of strategic significance;

- nuclear strikes by front weapons, carried out in accordance with the decision of the front commander in the interests of fulfilling his own missions.

All of these strikes must be carefully coordinated and considered in the plan of a front offensive operation with a view to the fact that they should complement one another during the suppression and destruction of various enemy groupings, his firing means, and rear installations.

A detailed elaboration of the questions of the use of front nuclear/missile weapons will now form the basis for the planning of a front operation. We must proceed from the fact that with the modern scale of use of nuclear/missile weapons, they can no longer be considered only as a means of supporting the combat operations of the troops. Within the framework of the front, this weapon now becomes the primary and decisive means of combat which determines the possiblity of the fulfilment of the majority of the tasks of an offensive operation. Therefore, the concept of the delivery of front (army) nuclear/missile strikes appears to be the most important pivotal element of decision and plan of the operation. The operations of division ground troops must be planned in conformity with the selected method of the use of the nuclear/missile weapon and not the reverse.

It is quite clear that under such conditions the purposeful planning and conduct of operations will appear impossible without an early preparation of the sequence of the use of nuclear/missile weapons in the entire depth of an operation with regard to the probable

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

perspectives of its development.

As the experience of exercises demonstrates, it is advisable not only to plan the tentative distribution of nuclear/missile weapons according to axes and the tasks to be fulfilled, but also to determine, to the extent possible, the main massive nuclear/missile strikes which will be organized and conducted by the front with centralized use of both front and army weapons. It is necessary to establish the tentative number of such strikes, and when, for what purposes, and approximately what expenditure of nuclear ammunition will be used.

It is apparent that in the course of the operation there will not be so many such strikes (generally not more than 5 to 7), for, as experience has shown, a front cannot conduct more than one or two massive strikes within a 24-hour period. It is clear that of all these strikes only the first massive strike (primarily counter) will be carefully planned and organized in advance in all details, including the selection of specific targets (main and alternate), determination of sequence, the timing, and the nature of their neutralization. As regards the remaining massive strikes, they can and must be worked out only in a general way with determination only of the main tasks to be fulfilled, tentative periods for their implementation, and the approximate expenditure of nuclear ammunition. This will permit us to avoid the unexpected and will provide the front troop commander with the opportunity of having a sufficient amount of weapons in readiness at the necessary moment for a decisive influence on the situation.

The operations of front ground troops, closely combined with the massive use of nuclear/missile weapons in operations of the initial period of a war, will most likely take the form of swift and deep strikes delivered by separate tank groupings on independent axes with a mass landing of tactical and operational airborne forces in the depth and a broad movement of individual units by helicopters for rapid surmounting of zones with high radioactive contamination and also for the reinforcement of those troop groupings which have burst out ahead. As a rule, such a swift offensive will be closely combined with the simultaneous conduct of sustained defensive

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

battles and engagements on other axes with energetically advancing enemy large units which have made a deep penetration. As a result, a very complex interlacing of combat formations of ground troops is created in a majority of cases. The engagement will develop on a very large front, but in depth it can simultaneously envelop a territory of several hundreds of kilometers. The combat will take on an extraordinarily sharp character for seizure and retention of the operational initiative. Success will accrue to the side which, in a shorter period of time, achieves sizable operational results, uses its nuclear/missile strikes more effectively, more quickly captures the principal areas where aviation is based, and especially the launching sites of enemy operational - tactical missiles. The front troops must not permit a deep penetration by enemy groupings and at the same time they must break through, in the gaps between the zones of contamination formed, and sometimes directly across these zones, in short time limits and at a high tempo, to the largest political and military-industrial centers of the enemy, to areas where his reserves are being formed, to ports, and also to the other most important objectives of the operational and strategic rear. At the same time it is necessary to ensure the decisive destruction of both these retreating enemy groupings and the new enemy groupings being deployed in the rear. Front tank troops must break up these groupings, force them into impassable areas or zones of contamination and liquidate them piecemeal.

As a rule, a surprise counterblow of several groupings from various directions in combination with massive nuclear strikes by army and front missiles must be organized for that. To aim for the encirclement of large enemy forces in such a situation will obviously be inexpedient. Indeed, to carry out such a maneuver will be extraordinarily difficult because of the impossibility of a reliable blockade of the encircled troops, as was correctly stated in the pages of the Special Collection of the Journal, "Military Thought" by General Gastilovich and General Tolkonyuk. Therefore, instead of encirclement with formation of a "ring", the advancing troops must strive to capture only the most

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

important centers of transportation on the flanks and in the rear of the enemy, to restrict his maneuver by specially formed zones of contamination, to disperse the isolated grouping into units and then, meteorological conditions permitting, suppress them with powerful surface nuclear strikes.

The question of the operational makeup of front troops in an offensive operation of the initial period of a war stands in a category of its own. In view of the increase in the scope of possible enemy use of weapons of mass destruction, the necessity arises for further dispersion of forces and equipment. However, this does not mean that one can extend troop combat formations ad infinitum and undertake an offensive on an operational axis with only separate divisions or even just units. In all situations, the front and army must resolve their tasks not as individual large units but as operational groupings, each of which can have up to three or four divisions. Only in such a situation can one ensure continuous and rapid accumulation of forces from the depth, timely replacement of troops who have lost combat effectiveness, and a sufficient force for striking the enemy.

In this respect, General Gastilovich adheres to a different view in his article. He believes it advisable to repudiate completely the term "strike group" and proposes to introduce the term "offensive of separate divisions on independent axes". Thus, the idea of isolated strikes by small forces is being advanced.

On the basis of the experience of exercises conducted in the Group of Troops (Gruppa voysk) and also in other military districts, we believe that such a method of operation even with very large-scale use of missiles with nuclear charges of high yield will hardly be correct. Of course, if we count on an unhindered advance of troops through devastated territory, then an offensive by separate divisions can provide some results. But, if we proceed from the fact that the enemy will be able to preserve a certain portion of his forces and will attempt to undertake vigorous offensive operations, then the proposed method in conducting the offensive can hardly lead to significant success.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

We agree with the fact that our division, in the event it is equipped with tactical nuclear weapons, will be a powerful force. But can one division destroy one or two enemy divisions in a short time under conditions of direct contact when the use of high-yield nuclear ammunition is excluded? Can we ensure sufficient viability of such a "small grouping" and a continuous increase of its efforts from the depth? In the final analysis can we, with one large unit, simultaneously resolve several varied tasks, which, as a rule, will arise on any operational axis?

Obviously, not isolated divisions but operational groupings are needed for this. Depending upon the situation, the operational grouping may be formed and may operate in different ways. In the absence of direct contact with the enemy the gaps between the individual large units included in its composition may reach 10 to 15 kilometers or more. But in the course of battle the troops of an operational grouping must operate as an entity, maintaining close tactical and nuclear-fire liaison with one another. The fear that they can be destroyed by one strike of a nuclear missile with a megaton charge are groundless because the use of such a weapon is impossible under conditions of a dynamic engagement with direct contact by both sides in the tactical depth. As regards nuclear strikes of small and medium yields, they can inflict the same loss on the troops whether the divisions are operating within the composition of the grouping or if they are separated one from the other.

The matter is somewhat different as regards the disposition of operational and special reserves. We believe that they cannot be concentrated on the most important axes, as was done previously. Obviously, a great portion of the reserves and second echelons, will have to be dispersed along the entire front zone, avoiding areas within whose limits there might be objectives which are convenient targets for a nuclear/missile assault by the enemy (for example, large industrial centers, centers of transportation, ports, etc.).

The echelonment in depth of reserves must be sharply

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

increased: in an army, up to 200 kilometers at least and in a front, up to 500 kilometers. It is true that at first glance such norms under the high performance conditions of modern engagements may appear to be excessively high. But one must keep in mind that these are the ultimate zone borders for the disposition of reserve large units, and that the immediate reaction to sharp changes of the situation can now and, obviously will, be carried out first of all by massive use of nuclear/missile means. At the same time a large echelonment in depth of the reserves will permit them to escape destruction by high-yield nuclear strikes, since it will afford an opportunity to enlarge the gaps between large units up to 30-50 kilometers and deploy each division over an area up to 300 square kilometers if part of the army reserve and up to 500 square kilometers if part of the front reserve.

Now, concerning the second front echelon. Is it necessary? General Gastilovich believes that it is not. In modern situations, according to him, only separate divisions can be introduced into an engagement from the depth. If it is necessary to overcome strong enemy resistance or to switch efforts quickly to a new axis, this must be accomplished principally by "concentration of nuclear weapons and their delivery means" and not by introducing strike groupings into the engagement.

We believe that such a juxtaposition of various front forces and weapons in an operation of the initial period of a war is not quite correct. In fact, a rapid change in the situation, as a rule, can be achieved only under conditions of a coordinated delivery of both nuclear/missile strikes and ground troop strikes. Every attempt to resolve a task by nuclear means or by ground troops alone is doomed to failure.

There are not sufficient bases to assume that separate divisions brought into an engagement in isolated axes after a massive nuclear assault can seriously influence the situation, particularly during the critical moments of the development of the operation. During battle with a strong enemy grouping, this will impede the exploitation of success and can bring about

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

the piecemeal destruction of such divisions. The speedy resolution of a newly arisen important operational task can only be achieved, today as formerly, by the use on an operational axis of an operational grouping of troops composed of not one, but two or three and even four fresh divisions, united under a single army command. Consequently, a second echelon is necessary. However, its commitment into an engagement will apparently, have to be carried out somewhat differently now, on a wider front and, in a number of cases, not on one but on two adjacent axes.

How will the initial front operation of the initial period of a war under conditions of the Western TVD proceed as a whole? Naturally, this will depend on many factors, including the nature of the initiation of the war and the results of the first nuclear/missile strikes of both sides.

Enemy use of a large quantity of nuclear missiles and strategic aviation in the first strike can undoubtedly, inflict enormous material and moral damage on the opposite side: seriously weaken its military-economic potential, disrupt the established troop groupings (if they are not sufficiently dispersed), disrupt the mobilization build-up of the armed forces, etc. However, this still does not mean that the fate of the war, its initial period, or even the first strategic operation will be decided by such a strike.

Experience of exercises shows that with thorough preparation of the country for war and with sufficient dispersion of missile launching sites over a large territory, a surprise attack does not at all deprive the troops of the possibility of inflicting a nuclear/missile counterstrike of great force.

It should be taken into account that modern means already permit the detection of the flight of missiles when they are several thousand kilometers from target. Therefore, each side will have time to give the appropriate commands to missile units and to organize as a counter-strike the first launching of ready solid fuel missiles before the enemy is able to put them out of action.

One can also anticipate that the ground troops,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

subjected to an attack, will often retain the capability for active operations, thanks to the high results of the counterstrike and will be in condition to conduct a successful fight for the seizure and retention of the operational initiative. In any case, on the main strategic axes of the Western TVD it is necessary to aim primarily for immediate development of an offensive /3 or 4 words missing/ of the rapid exploitation of the results of a nuclear/missile counterstrike.

However, one cannot exclude a situation in which the results of an enemy nuclear assault will be so serious that there will be practically no forces for a quick shift to the offensive. In such circumstances the efforts of commands and staffs must be directed at bringing their forces back into order as quickly as possible (in any case before the enemy), preserving the initiative in the use of operational-tactical missiles and, at the most favorable moment when the enemy is weakened to the extent possible, at beginning vigorous offensive operations in decisive directions with the newly created groupings. The determination of such a moment requires great skill. This requires precise calculation, the ability to evaluate correctly our own capabilities and the capabilities of the enemy, and the most expedient planning of the targets for repeated nuclear strikes, of the deploying time of friendly strike groupings, and of the sequence of their entry into combat.

Depending on the level of operational readiness of the antagonists, the effectiveness of the first nuclear/missile strikes, and the decisions reached, the shift to the offensive by front ground troops can be carried out under conditions of a deep invasion of enemy strike groupings at the moment of their deployment on the border or, finally, in the course of the creation of such groupings in the depth. In all of these cases, the front troop offensive apparently will take the form of a series of large meeting engagements waged simultaneously in several directions.

Success on at least one of these axes must be achieved quickly and developed with utmost resolution in depth. Front strike groupings (especially the tank

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

units included in their composition)must advance swiftly to the objectives destroyed by strategic nuclear strikes, split up the enemy reserves which are being moved up, and in cooperation with airborne forces must destroy them piecemeal. For this, the average rate of troop advance must reach 70 to 90 kilometers and for tank divisions - 100 to 120 kilometers per 24 hours; when conducting strategic nuclear/missile strikes on the TVD this can be considered entirely practicable.

The correct planning of the battle for fire superiority over the enemy and skilful organization of the fire support of troop operations will have vast significance for the attainment of a high offensive impetus.

During World War II the basic tasks of fire support were resolved principally in the process of conducting artillery -- air preparation and artillery -- air support of an offensive. Now, fire support greatly exceeds these limits in its aims and nature. Its basis will not be fire by conventional means of combat but primarily powerful nuclear/missile strikes, delivered on the entire depth of the enemy's formation.

In view of this, artillery and air preparation and support of the offensive as previously understood lose their significance. Actually, they are being converted into only one of the composite elements of fire support and not the principal one at that. In the majority of cases their task will be primarily the preparation and support of assaults by individual units and subunits. Therefore, they will find their basic use at divisional and regimental level.

In the army, and more so in the front, scope, fire support of an offensive operation as an operational concept will include: participation of front missile weapons in massive strategic nuclear/missile strikes organized by the Stavka RVK in the TVD, nuclear-fire preparation and nuclear-fire support of advancing troops.

The tasks of nuclear-fire preparation and support will be carried out by front, army, and organic missiles and also by light fighter-bomber aircraft, tube and light rocket artillery in close coordination and calculated to

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

ensure the possibility of conducting a continuous troop advance with average tempos of 70-90-100 kilometers in a 24-hour period. In this event, the targets of fire strikes are not only enemy troops and fire means in the tactical and near operational depth, but also his missile units, aviation, tactical and operational reserves, control points, and also installations of the operational rear.

Because of the frequent and sharp changes of situation characteristic of the initial period of a nuclear war, the inevitable dropping out of action of individual elements of the operational organization and because of the possible establishment of extensive zones of contamination with lethal levels of radiation in the directions of the troop offensive, wider maneuver of forces and weapons than formerly will have to be conducted in the course of a modern front offensive operation.

The front troop commander must be constantly ready to transfer his efforts from one direction to another, in order to reinforce one troop grouping or another. This will be achieved primarily by means of a rapid reorientation of missile weapons and the maneuvers of their strikes with nuclear warheads. But reorientation solely of missiles does not provide the proper result in many cases, particularly since in mobile forms of combat there often will not be suitable targets either in the tactical or operational depth for the delivery of a large quantity of nuclear/missile strikes.

Therefore, as a rule the maneuver of nuclear strikes must be inseparably combined with the maneuver of ground troops, their forces, and weapons.

Of course, a rapid transfer of troops over considerable distances is sometimes linked with extraordinarily great difficulties. An especially severe situation can be created in this respect during the initial period of a war when many lines of communication are put out of action. Great skill is necessary under conditions of mass destruction to lead large units and units over territory with extensive zones of contamination during continuous activity of enemy aircraft overhead. Regrouping of troops in such a situation will require exceptionally precise control of the columns, flexible

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

maneuver of them, repeated changes of routes of movement, and the conduct of extensive obstacle-clearing measures. Everything will have to be taken into account: the condition of the terrain, the radiation situation, the destruction created fires, the probable direction of the spread of radioactive dust clouds, etc.

In many cases all fixed bridges over both large and medium rivers in the directions of the movement will be knocked out of service. As a result, the laying of new river crossings will be required and quite often, the organization of crossing of river lines by tanks along the bottom. Naturally, all this cannot but affect the march tempos. In any case, estimates on the possibility of accomplishment by divisions /2 or 3 words missing/ in the course of the operation, daily marches of 300 to 350 kilometers can become practicable only with very well calculated engineering support, reliable screening of the columns from the air and also, with careful organization by the commandant's service, and the equipping of all large units with their own ferrying equipment.

The complex conditions of maneuver and the conduct of combat activities in front operations of the initial period of a nuclear/missile war require further improvement of the organizational structure of our ground troops.

Experience of exercises shows, for example, that tank armies of the existing composition will experience serious difficulties in their operations in almost all strategic directions under the conditions of the Western TVD. The inadequacies of motorized infantry sharply complicate their forcing rivers, the capture of densely populated and wooded areas, the overcoming of zones of great destruction, etc. Therefore, it is advisable to have tank armies composed of three tank and one motorized-rifle division. Eliminate heavy tank divisions as a permanent element from the tank army (TA) composition. Keep them in the capacity of large units of the High Command Reserve for the reinforcement of troops in separate directions.

Concurrently, the question of the future reorganization of tank divisions also arises. Postwar experience

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

persistently bespeaks the advisability of conversion of tank divisions of T-55 type tanks. It is necessary to eliminate the heavy tank regiment of the tank division from the division.

In its stead, we should have, in the army composition, a heavy tank brigade as a reserve of the army commander for reinforcement of tank divisions in an offensive or defensive operational situation. The division artillery should be converted to self-propelled rocket artillery of the type of the separate battalions of the Rocket Artillery (RA). The entire parkofarmored carriers should be replaced with amphibious armored carriers. The division TOE should include a regiment of Mi-4 helicopters, instead of a helicopter flight (zveno), not for liaison, but for the support of combat operations of the division in the operational depth.

The necessity has arisen to introduce serious changes in the structure of the operational and troop rear service areas as well. Practically all the command-staff exercises of the past years have convinced us that despite the reorganization already carried out, the rear cannot yet properly support combat activities of the troops in operations of the initial period of a war. Because of the high tempos of the offensive of the troops and the mass destruction of communication lines, the existing system of supply and evacuation, based mainly on the use of rail and automotive transport, and the intended successive transshipment of cargo to front and army depots, is not justified.

Usually materiel for the troops begins to arrive already by the 3rd to 5th day of a war with great irregularity. As a rule, rail transport is put out of action. The work of automotive transport becomes difficult because of its limited quantity. The excessive bulk of rear organs also continues to affect adversely the activities of the rear. The army mobile base, for example, is now calculated for a volume of up to 5,200 tons of various cargo. Meanwhile, army transport is not in a position to pick up this quantity of supplies in one trip. Therefore the base, as a rule, falls behind and is not able to cope with its tasks.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The complicated tasks in the organization of materiel-technical support of front operations of the initial period of a war require the vigorous elimination of these deficiencies. We believe that the basic means of supply and evacuation at the front and army levels must be air transport, automotive transport and only partly railroad transport. In connection with this, it is advisable to include heavy-duty helicopters and aircraft in the TOE of division troops at the rate of a division of Mi-4 and Mi-6 helicopters to an army and 3 or 4 air transport divisions to a front.

It is necessary to equip fuel dumps with field pipelines. For supplying fuel to the troops and servicing tank columns in the course of combat there should be "tanker" helicopters of large capacity with which a net of GSM (fuel and lubricant) distribution points could be organized in the operational depth and in the theater of military operations. By so doing, the dependence of materiel-technical supply on communication lines is eliminated and the necessity of excessive closeness of supplies to the troops is eliminated.

At the same time, it is necessary to review completely the system of supply and evacuation with an eye to abolishing the intermediate links. Previously, these were necessary because the supply arm was restricted by the possibilities of automotive transport turnaround. With the shift to a combined system of supply and evacuation, this principle does not justify itself. Therefore, in our opinion, there is good sense in organizing the supply of large units and units with all sorts of combat provisions and supplies directly from front depots located at various distances from the front line. In this way the reduction of supply time will be ensured and conditions will be created for flexible maneuvering of supplies on a front based on specific conditions in the conduct of combat operations by the various troop groupings.

Armies should maintain only a reserve of materiel (not more than 2,000-2,300 tons) which the troop commander could use to affect the support of the troops operating in the directions of the main strike.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

It is quite clear that the questions enumerated do not by any means exhaust the entire substance of the problems arising before us in connection with the study of the peculiarities of the preparation and conduct of an operation in the initial period of nuclear/missile war. But their statement and correct solution, in our opinion, can promote further development of military-theoretical thought, and the investigation and elaboration of new, more perfected forms and methods of troop combat operations.

Some Problems of Modern Operations

by Lieutenant-General I. Tolkonyuk

The problems of conducting military operations when both sides use nuclear weapons have already been under study in our system of operational training for several years.

A good deal is being written on these problems in our military press. However, in practical operational preparation, in the pages of the press and in military-scientific work, these questions are examined very timidly, which is out of keeping with the conditions of nuclear warfare. The matter is not taken beyond the adaptation of old forms and methods to new conditions, although the discussion should be concerned with essentially new categories of military affairs. It seems that the time has come to sacrifice boldly many of the theses from which the basic principles of operational art and tactics have developed.

Military art is confronted with the fact that nuclear/missile weapons bring strategic significance to the fire strike (ognevoy udar). There are many reasons for supposing that it will often be possible to crush the enemy's will to resist only by the strikes of nuclear/missile weapons. This phenomenon, which the nuclear age has brought to mankind, confronts states and their armed forces with a series of the gravest problems in the realm of military activity.

For this reason, our military thinking must work deeply on all the problems connected with the preparation and conduct of modern nuclear warfare. Once we have fully resolved these problems we can discuss forms and methods of conducting military operations. First of all, our nuclear/missile strategy must be worked out most precisely, since it is the strategic nuclear/missile weapon which will be decisive in the achievement of victory. Then, on the basis of the strategic requirements for the accomplishment of strategic tasks, and for the exploitation of the results of the nuclear/missile strategic operations being conducted, it will be necessary to work out the methods and forms of conducting combined operations with the types of armed forces, which are the subject of examination in the field of operational art.

Along with the study of the problems of nuclear/missile operations and the use of weapons of mass destruction in zones of military operation, it is necessary to make a radical reexamination of the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

problems connected with the use of ground troops and naval forces, whose utilization and operations must correspond to the conditions created by the use of weapons of mass destruction.

The resolution of questions of operational art and of questions on the preparation and conduct of modern operations is possible only on the foundation of solutions to the problems indicated above.

The absence of even slight experience in nuclear/missile warfare demands the ability to foresee and to analyze; it demands deep and logical thinking. To glance unerringly into the future, making realistic allowance for the prospects of development of the means of armed combat - this, in our opinion, is the urgent task of our military theory.

In this article it is our aim to raise only certain problems of modern operations and to express our views on these problems briefly.

****

Nuclear/Missile Operations. The important strategic missions which, in the previous wars of our times, were accomplished by the conduct of a series of strategic offensive operations by ground, air, and naval forces, and which usually lasted a month or more, can now be accomplished in a very short period of time with the massed use of nuclear/missile weapons. Such an objective as depriving a hostile state or coalition of states of the capability to resist can be achieved, it would seem, in the course of a few hours or, at the outside, within a few days.

Of course, we do not consider that it is possible to capture the enemy's territory with nuclear/missile weapons. For this we will need mobile, well-trained ground troops with modern equipment, transport aviation, airborne troops, and troops supporting their operations.

It is possible, however, to deprive the enemy of the means of conducting war by nuclear/missile weapons alone if one has a sufficient quantity of the latter and knows how to use them to the greatest advantage.

The accumulation of a sufficient quantity of nuclear/missile weapons permits the conduct of so-called nuclear/missile operations for the performance of strategic tasks.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

What is meant by strategic nuclear/missile operations?

In our opinion, strategic nuclear/missile operations mean operations conducted by the missile troops at the decision and plan of the Supreme High Command, by the delivery of nuclear strikes aimed at depriving the enemy of the most important means of conducting war, at disrupting his civil and military administration and his national economy, and at breaking his ability and will to offer further resistance.

The execution of such operations will probably be the most important and the most crucial act of a future war. This is why the questions of preparing, supporting, and executing such operations must become --------- [remainder of sentence missing].

To learn how to prepare and conduct such operations is clearly the most vital task of our highest military echelons today; but this is a fairly complicated matter, not tested by experience, and entailing great responsibility. Here we have to deal with a very expensive means of warfare, which is used up in a short period of time, and which may not be available for repeating the operation in the event that the first attempt was unsuccessful.

The preparation of a nuclear/missile strategic operation and the attainment of its goals require first of all a good knowledge of the enemy's territory and of the geographical distribution and points of concentration of: modern means of warfare, primarily nuclear and missile industry; the storage points for nuclear ammunition (boyepripas) and missiles and the bases for their assembly and preparation; the main branches of industry; the launching sites of missile weapons and their control systems; the system of antimissile defense; transportation junctions; the most important points of concentration of manpower; sources of electrical power; the communication centers of state and military control, etc. On the basis of these data it is necessary to select targets in the enemy's territory whose destruction by nuclear strikes would paralyze the country and its military capabilities. It would seem that it is sufficient to destroy the most important points on the enemy's territory in order to place him in a situation in which it is impossible or senseless for him to undertake any measures whatsoever for continuing the war.

In planning such operations we should not scatter our resources, even if we are forced to deal with a powerful coalition of enemy states. It is necessary first of all to put out of commission the main partner

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

who represents the basic and directing force of the enemy camp; having lost the combat capability of their main partner, the satellite countries will be faced with the impossibility of starting or continuing a war.

To find the enemy's main links (zveno), whose destruction will paralyze his power -- this is the most important task to be performed by a nuclear/missile operation.

Thus, for the preparation and effective conduct of strategic nuclear/missile operations, it is necessary:

- to know in detail and to evaluate correctly the capabilities and the viability of the opposing side;

- to select the most vulnerable targets for a strike; of these, to take only the minimum necessary to accomplish the objective of the operation;

- to determine the amount and yield of nuclear charges needed to ensure the destruction of the targets selected;

- to determine the number of missile installations necessary for the delivery of the nuclear charges to the targets selected, taking into account accuracy (tochnost popadaniya);

- to choose the most suitable time for delivery of the strike;

- to organize control of the missile troops participating in the operation.

In the preparation of the operation, a very important place is occupied by the reconnaissance of the strike targets. An incorrect picture of the enemy, of his vitally important centers, or ignorance of the location of his most important means of warfare, can result in the strike being delivered against secondary targets, which will not achieve the objectives of the operation.

No less important is the proper selection and preparation of the missile launching sites to ensure the greatest effectiveness and convenience in launching. The stockpiling of nuclear charges, their delivery to the launching sites, and their mounting (stykovka) on the missiles represent a large volume of work of primary importance, requiring the expenditure of much time and effort.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Finally, there is the very complex question of organizing the control of the missile troops and of the launching and guidance systems of the missiles.

It is quite obvious that the preparations for a nuclear/missile operation are very complicated and demand well-trained personnel, a great deal of painstaking work, large numbers of qualified people, and the expenditure of colossal material means. However, the results that a successfully performed operation can bring are such that no means or efforts should be spared to achieve them.

The actual execution of such an operation will take a very short time. It appears that it will take from a few hours to a few days. In one instance, if sufficient means are applied, the strike may last a few minutes and will take the form of the launch of a particular series of missiles, in the form of an immense volley (zalp). In another instance, several series of missiles may be launched in the course of a few hours or even a few days, and the situation may then take on the form of a sort of missile duel.

It is quite possible that during the course of the war it will be possible to conduct only one strategic nuclear/missile operation which should determine the outcome of the war. If the enemy is a strong coalition, possessing powerful nuclear/missile weapons, we may land in a situation in which it will be impossible to carry out a subsequent nuclear/missile operation.

In any case, nuclear/missile operations must be carried out simultaneously in all, or at least in several, decisive theaters of military operations.

In presenting this question, we do not think that strategic nuclear/missile operations will have to be conducted with the aim of destroying all the hostile states composing the enemy coalition. This will be neither possible nor necessary. The operations must be directed at the main link of the enemy coalition, at his backbone. Once the enemy's back is broken he can be finished off by other means and methods.

After a strategic nuclear/missile operation has been carried out, it will be imperative to know the results of the strike immediately, to know to what degree the mission has been accomplished and how far the objective of the operation has been attained. Study of the results of a strike and of the degree of damage done to the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

enemy in a short time is an important job for the Supreme Command. It is needed so that the methods of carrying out further actions to exploit the results of the operation which has been performed may be determined and final victory may be achieved. To achieve final victory, it will be necessary to conduct offensive operations with ground troops, using mobile large units, airborne troops, naval forces and naval landing forces to crush the enemy troops who have survived or who have retained their combat capability, and to occupy the key positions in enemy territory. It follows, therefore, that nuclear/missile strategic operations will probably be the main link in the overall plan for waging a war. They must be conducted in close conjunction with the above-mentioned operations by ground and airborne troops and naval forces, who, in carrying out their tasks, must take maximum advantage of the effect of nuclear/missile strategic operations.

Modern Offensive Operations. The conduct of nuclear/missile strategic operations----/several words missing/ scales of aggressive operations by the ground troops. No matter what the effect of a nuclear/missile strategic operation may be, final victory can only be won by the occupation of the enemy's territory, or at least of the key positions.

Consequently, in order to attain final victory it is necessary for ground troops to carry out offensive operations. This is explained, first of all, by the fact that far from all the important targets and groupings of troops on the territory of the enemy will be destroyed by the strikes of a nuclear/missile operation, since to neutralize or to destroy everything with sufficient certainty would be practically impossible, and not even desirable. Whole areas, even very important ones, will remain untouched by strikes in these operations.

Even in those areas or in those theaters of military operations where the main targets and groupings of troops will be subjected to overwhelming blows during a nuclear/missile strategic operation, not everything will be destroyed, and it is mainly here that operations by ground troops are needed to exploit the results of the nuclear/missile strategic operation and to achieve final victory over the enemy.

In some theaters of military operations or in one section or another of these theaters and in one or another of the strategic or operational directions, nuclear/missile strategic operations will not

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

be carried out, because it will be either impossible or inexpedient. In all such instances, it will be necessary for offensive operations to be carried on by ground troops. These can take the form of offensive operations by a group of fronts or of an offensive by a front or by an army, carried out either within the framework of front operations or independently. In addition, combined operations may be carried out by missile and ground troops and by the navy.

Similar operations (without the use of nuclear/missile weapons) were carried out during the Second World War. Now, however, they will be of an entirely different character.

In the first place, for the performance of the tasks with which they are confronted in operations, ground troops now have at their disposal, in their missile equipment, the means for the use of high-yield nuclear weapons. This allows them, in the shortest possible amount of time, to inflict overwhelming blows against the enemy's weapons of mass destruction, against his basic groupings in the entire depth of their deployment, which can lead to the disorganization of the opponent's troops and deprive them of the ability to put up any serious resistance.

These blows can deprive the enemy of his missile installations, of the aircraft at his airfields, destroy his supplies of nuclear and missile weapons, put the airfields themselves out of commission, annihilate the basic groupings of the enemy's ground troops, and disrupt maneuver and control in a theater of military operations. In addition, this weapon makes it possible not only to inflict losses upon the troops of the enemy, but to destroy them completely, or at least to subject them to such strikes that they will lose their combat effectiveness completely.

In the second place, possessing weapons of mass destruction, ground troops will be in a position to crush the enemy's reserves in their mobilization deployment or buildup areas, preventing them from approaching the battlefield. This situation imposes entirely new conditions for combat with the reserves, and poses the question of the repulse of the counterstrikes and counterattacks of the enemy in a new form.

It seems that in future battles counterstrikes may be ruled out entirely, if the attacking force is able to organize the reconnaissance and destruction of the enemy's reserves correctly.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In the third place, the defensive maneuver of bringing up replacements and materiel to the field of battle can be prevented from the very outset of combat operations.

In the fourth place, the first nuclear/missile strike can, practically speaking, knock out of commission the basic elements in the enemy's system of troop control, which makes the unified and firm direction of the troops impossible.

In performing an offensive operation, a front must, above all, exploit to the maximum the results of a previously executed strategic nuclear/missile operation , as well as the results of their own nuclear/missile strikes. Thus, the goal of an offensive operation by a front must be the quick seizure of the key positions on the enemy territory so that he has no opportunity to recover from the blow and to carry out substantial counteraction. The most important task of the troops of the front will be the annihilation of those groupings of troops and weapons of mass destruction which have survived the nuclear/missile strike or have retained their combat effectiveness.

The depth of front operations in the recent past was primarily determined by the front's ability to suppress the enemy with a large degree of consistency in the given depth, by the depth of the operational formation of the enemy, by the permissible elongation of the rear areas (rastyazhka tylov), by the lag in the basing of airfields, and by the degree of effort and exhaustion which the troops were permitted to sustain. For the successive execution of intermediate tasks the front was allotted definite boundaries for the immediate and follow-up missions. Within the framework of a front operation several successive offensive operations by armies were carried out.

The most important form of operation was the encirclement of the basic grouping of the enemy and his subsequent annihilation. This was done in order not to give the enemy a chance to withdraw his grouping to the rear area, put it in order, reinforce it with reserves, and to organize further operations, i.e., to make it impossible for him to escape destruction or annihilation. The most important phase of the operation was breaking through the enemy's defense.

How do these questions appear in modern operations? Since modern weapons permit a consistent degree of annihilation (and not just suppression) of the groupings of the enemy in the entire depth

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

of his deployment, the offensive must encompass the entire depth at once. For this purpose, the mobile groupings of the front must follow the nuclear/missile strikes and proceed in the most advantageous directions into the depth of the enemy's deployment to chosen objectives or to selected areas. Landings of airborne troops must be made immediately to capture objectives located deep in the interior, and in a coastal area amphibious landings must take place. Part of the troops must be moved by air. In such a situation combat focal points will form in the entire depth of the operational direction along which the offensive operation is being carried out. Only in this case can the results of nuclear/missile strikes be exploited effectively and in good time.

From this, it seems to us that the principles for planning a front offensive operation which we accept at present are outdated and no longer correspond to modern demands.

The division of the overall task of a front into immediate and follow-up territorial categories, to be carried out in sequence, does not permit the fullest and most effective exploitation of the capabilities of today's new means of combat. In planning an operation, it would appear to be more expedient to envisage two goals -- the immediate and the final goal of the operation.

The immediate goal of a front offensive operation should be the destruction by nuclear/missile weapons (and other weapons of mass destruction) of the enemy's weapons of mass destruction, the annihilation of the basic groupings of his troops, the destruction of his communication lines and radiotechnical systems, disruption of his government and military controls, the liquidation of his supplies of materiel, and the disorganization of the population, i.e., the liquidation of the enemy's ability for organized resistance.

The final goal of the operation must be the capture of key positions or vitally important areas on the enemy's territory, i.e, the occupation of his territory.

In order to reach these goals the main operational problems for resolution by the commander of the front must be; to define the objectives whose destruction by nuclear/missile weapons should deprive the enemy of the capability to resist or counterattack and to determine the yield, types, means, timing, and method of these strikes. The resolution of these problems will in fact also resolve the main strike in the operation.

1.3(a)(4)

[redacted]

1.3(a)(4)

After this, the commander of the troops of the front should determine the areas or objectives which must be captured by ground or airborne troops, or by troops carried by aircraft and helicopters, or, in a coastal area, by amphibious landing forces, in order to envelop the entire depth of the enemy's territory in the shortest possible time. He must determine the initial (iskhodnyy) grouping of the ground troops and the direction of movement of the mobile groupings for the capture of selected areas or objectives, and for the annihilation of surviving groupings of enemy troops, or of those which retain their combat effectiveness. Further, he must coordinate the timing and the tasks to be performed by all arms of troops, and resolve all the remaining questions connected with the preparation, organization, and execution of the offensive operation.

In this connection we must bear in mind that there is no longer any need to establish solid groupings of troops along a narrow front, as was the case in the past, when a front was forced to do this in order to penetrate the enemy's defense, since it is unthinkable that the enemy, under modern conditions, will establish any harmonious (stroynyy) system of defense with the continuous front and boundary lines typical of the last war. Supposing that such an attempt were to be made, it would lead to the annihilation of the defenses by nuclear weapons, and the entire front would in any case be destroyed.

On the whole, however, there will be no continuous fronts, and consequently the penetration of the enemy's defenses on an operational scale has already passed into history. It is possible that in isolated cases there will be a penetration of the enemy's defenses, but this can happen only in a tactical sense.

Proceeding from what has been said above, it is also necessary to review the matter of army offensive operations. It seems to us that there is no need for the combined-arms and tank armies operating within the composition of a front to execute several army operations in the framework of an offensive by the front. The tank army must penetrate to the entire depth of the front operation, and occupy that part of the opponent's territory which is farthest from the line of departure. The combined-arms armies should be given the task of operations throughout the depth of the front operation, or be assigned to occupy a specific portion of territory within the boundaries of the front operation. Airborne and amphibious landing forces, as well as troops being moved by air, must also occupy specific centers or areas in the interior of the enemy's territory.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The tempo of the operation is a different matter. Measuring the tempo of a modern offensive operation by the daily advance of the ground troops is senseless, in our opinion, because this will not be in accordance with the decisive conduct of the operation, and will not allow the timely and effective exploitation of the results of the strikes of nuclear/missile weapons in the entire depth of the operation . The duration and procedure of conducting the operation -- these are the main issues in the calculations, rather than the tempo, in its former meaning. A battle will split into separate focal points of combat, dispersed over a large area, and therefore the planned advance of a mass of ground troops as a continuous front is unthinkable.

The most important and perhaps the most complicated element of modern offensive operations will be, it would seem, the preparation of the operation. It will include an entire set of complicated measures, large in scope, and labor-consuming, which will need a definite, and probably lengthy, period of time. Therefore, in studying modern operations, our operational art must pay special attention to the problems of the detailed preparation of an operation, because its successful execution and the results obtained will depend entirely upon its preparation. Hence, in our view, a modern offensive operation should consist of two phases; the preparatory phase and the phase of execution of the operation. These periods must be determined by the General Headquarters (Stavka) of the Supreme High Command, in close coordination with the strategic nuclear/missile operation being prepared, in order to coordinate and unite the efforts of the forces and means of those participating in the nuclear/missile strategic operation, and of the ground troops operating in one or another strategic direction. In addition, it appears that the nuclear/missile means of fronts will often be detailed for participation in and execution of a nuclear/missile strategic operation being carried out by the General Headquarters with the forces of missile troops of strategic designation.

It is plain that the preparation of such an operation is a complicated and crucial process which should start at the moment the front receives an assignment to carry out an offensive operation and end at the moment the signal is given to deliver the nuclear/missile strike. This phase will probable take longer than the actual phase of execution of the operation.

The phase of execution of the operation should begin at the moment the signal is given to begin the nuclear/missile strike, and end at

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the moment the final goal of the operation is reached. Now, when nuclear/missile weapons have become the basic means of destruction of the enemy and the decisive factor in achieving victory over him, it would be incorrect, to say the least, to call the beginning of the activities of the ground troops the beginning of the operation, because the start of artillery preparation, or the shift to the offensive of the ground groupings, does not represent the main phase of the operation; these activities will be of a subordinate nature in comparison with the operations of the missile troops by whom the destructive missile strikes will be inflicted on the enemy.

The first operations in a future war will be of a decisive nature, and the ultimate outcome of the war will probably depend on their successful execution. Therefore, the primary and urgent [one or two words missing]--of military thinking is the most thorough elaboration and the theoretical solution of all the problems connected with their preparation and execution.

The Materiel and Technical Support of Modern Offensive Operations. The advance of ground troops in an operation will undoubtedly be carried out under difficult circumstances. Supply bases, depots, communication lines, and other targets in the rear area may be subjected to heavy nuclear strikes by the enemy; the operation of railroads may be disrupted and delivery of materiel and technical supplies by air may be impeded. Thus, one can not count upon being able to supply troops with materiel according to plan during an operation which has already started. In this connection, both missile troops and ground groupings must have all the necessary materiel supplies at their disposal before the start of combat operations. These supplies must be dispersed, well concealed, and camouflaged, in areas which would be convenient, and from which issue to the troops at any time can be ensured. As much of this material should be stockpiled before the start of the operation as would be needed to carry the entire operation through to its ultimate goal. In addition, provision must be made for a specific reserve of these supplies, also concentrated in convenient areas, from which they could be delivered to the troops by motor transport and by helicopter. Fuel should be supplied mainly by pipeline in order not to burden other, more vulnerable, means of transport with its delivery.

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Initial Period of a Future War and the Special Features of the Conduct of Military Operations During This Period", by Colonel-General N. Pavlovskiy.

This article appeared in the 1961 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. It is distributed only within the Ministry of Defense down to the level of Army Commander.

The Initial Period of a Future War and the Special Features of the Conduct of Military Operations During This Period

by

Colonel-General N. Pavlovskiy

Our Party and the Soviet Government are striving to achieve the lessening of international tension, the curtailment of the arms race, and the prevention of war by conducting a peace-loving foreign policy. The Soviet Union is doing everything which lies in its power to achieve this goal. One of the convincing proofs of this is the visit of our governmental delegation, headed by Nikita Sergeyevich Khrushchev, to the 15th Session of the General Assembly of the United Nations.

However, as is known, the peaceful policy of the Soviet Union is clearly not to the taste of the aggressive circles of the imperialist states which have grouped themselves around the United States of America, who continue, as they have in the past, to conduct a policy of exacerbating international relations, of stepping up the arms race, and of preparing for a new war. As soon as the efforts of the Soviet Union and of other peace-loving states directed toward the lessening of international tension begin to produce perceptible results, these states once again bring the world to the brink of war by the most extreme measures. In the last analysis, this can lead to the outbreak of a new war. History is already acquainted with many such examples so unfortunate for the fates of nations.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Under these circumstances, the main task of the Armed Forces of the Soviet Union is the further improvement of combat readiness for immediate operations, with the aim of disrupting the attack of the enemy and of crushing him decisively.

The constant qualitative changes in the development of the Soviet Army and Navy which are taking place before our very eyes call for a great deal of work on the further development of Soviet military art by all generals, admirals, and officers, in accordance with the present-day requirements for the conduct of armed combat.

One of the most important problems of military science, the study of which is given much attention both in our country and abroad, is that of the initial period of a war. This is, of course, fully understandable, since the outcome of a future war will depend to a considerable degree on the results of the first clashes, the first strikes of the combatants. For this reason, the study of the problems of the initial period of a war and the preparation of the types of armed forces for the conduct of military operations during this period have great theoretical and practical significance for us.

But in order properly to understand, and to resolve the problems of the initial period of a future war, we must have a clear conception of the nature of this war. We will therefore try, if only in a general way, to review this problem.

The nature of a future war. In examining the nature of a future war one must first of all take into consideration the existence of and struggle between the two world systems, the socialist and the capitalist. In spite of the tremendous efforts of the Soviet Union to conduct a policy of peaceful coexistence, which we have touched on earlier, the struggle of these two systems, under certain conditions, may become sharply

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

exacerbated, and the imperialists will then attempt an attack on the USSR or on the other countries of the Socialist Camp, which represent the chief obstacle to the achievement by the imperialists of their aggressive goals. Such an attack can scarcely be confined to a local war. It will most probably lead to a world war in which the states belonging to the two opposing world systems will take part.

Consequently, in speaking of the possible nature of a future war, we start from the premise that it will be of a world-wide, coalition character. In this war, because of the existence of irreconcilable contradictions between the socialist and capitalist systems, any sort of compromise will be almost impossible. Both sides will pursue the most decisive political and military goals - they will strive to achieve total victory.

To wage such a war powerful modern weapons (sredstvo borby) and massive armed forces will be needed, together with the utmost exertion of the entire moral and physical strength of the peoples and economies of the belligerent states.

In recent years, the opinion has been expressed in the West, and sometimes even in our own country, that a future war will be of short duration and may be concluded in the course of several weeks, or even several days. Such prognoses are based on the fact that modern weapons are capable, in a short period of time, of inflicting such heavy damage upon the enemy that it can be presumed that he will be unable to continue the war; thus, the objectives of the war can be achieved considerably more rapidly than has been the case in past wars.

At the same time, a contrary point of view also persists, whose proponents claim it as axiomatic that a future war, like the world wars of the past, will assume a drawn-out character.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In considering these points of view, Marshal R. Ya. Malinovskiy, the Minister of Defense of the USSR, in his report to the All-Army Conference of Secretaries of Primary Party Organizations in May 1960, pointed out that both suffer from the fact that they solve the problem of the duration of a war in a one-sided fashion. It would be more sensible not to go to extremes in this question. We should, the Minister of Defense said, develop and perfect weapons and methods of armed combat primarily with a view to achieving victory over the aggressor in the shortest possible time, but at the same time it is also necessary to make serious preparations for a lengthy war.

We term a future war a missile/nuclear war, since the primary means of destruction will be nuclear weapons, and the chief means of delivering them to the target will be missiles of various types and designations.

The employment of nuclear weapons and of other means of mass destruction will impart a tense and desperate character to a war. In order to seize and retain the strategic initiative, and also to ensure the achievement of the aims of the war, each side will develop vigorous military operations by all the means at its disposal from the very beginning of the war, in order to inflict upon the enemy the maximum losses in personnel and material resources, and also in order to effect the greatest possible destruction on his territory.

The military-geographical disposition and the large territories of the countries which make up the military coalitions, and also the long range of modern means of destruction, make it certain that the war will be waged over huge areas. The war will be waged not only in the European and Asian theaters, but will embrace other continents and wide naval theaters of operation. Military operations develop

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

both on a front and also deep in the rear of the belligerent states. The tremendous spatial scope (prostranstvennyy razmakh) of the war, the necessity to protect and defend objectives and lines of communication far to the rear, and also the probable growth of losses, will lead to a situation where the strength of the armed forces in a future war will far exceed those in all past wars.

The increase in the combat capabilities of all types of armed forces brought about by the swift development and widespread introduction of new means of destruction will lead inevitably to a change in the methods of waging war. In this connection, particular significance for our armed forces in the achievement of the goals of the war will lie in the operations of missile troops, the decisive delivery of mass nuclear/missile strikes designed to destroy and to annihilate vitally important objectives deep in the rear of the enemy, the destruction of the basic groupings of his armed forces, and the suppression of his will to resist.

The effective antiaircraft defense of troops and objectives in the rear of the country will have a no less important significance for the successful conduct of the armed struggle. It must be capable of giving timely warning of the threat of a nuclear attack, and of detecting and destroying in the air the missiles and aircraft of the enemy. It can be stated immediately that the success of nuclear/missile strikes on the one hand, and of the operations of the antiaircraft defense forces and weapons on the other, particularly at the beginning of a war, will determine its further development to a great extent.

In the general course of armed conflict in a theater of military operations, an important role will be played, as in the past, by the activities (operatsiya) of the ground troops, the most

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

characteristic features of which will be: the widespread use of nuclear weapons and of other means of mass destruction; exceptionally high mobility and dynamism (dinamichnost) in the combat operations of the troops; an increase in the spatial scope and average speed of operations; the absence of solid fronts and the conduct of combat in a series of directions, at times in areas isolated from one another, at varying depths, frequently with the conduct of large head-on clashes (vstrechnoye stolknoveniye).

In the naval theaters of operation a no less decisive and intense struggle will develop between the forces of the two sides. This struggle will be directed toward the destruction of the enemy fleet at sea and at its bases. Groupings (gruppirovka) of warships, above all, of missile submarines, aircraft carriers, naval bases, and ports of the enemy will be subjected to strikes by naval forces employing all modern weapons. Along with this, naval forces, chiefly submarines, will wage continual war on lines of communication and in some cases will deliver nuclear strikes on targets of military and economic significance in coastal areas.

The widespread employment of nuclear weapons in a future war, primarily through the use of missiles, but also from aircraft and submarines, together with the highly mobile operations of ground and airborne troops, will permit the performance of tactical, operational, and strategic tasks in shorter periods of time than has been done in the past. Here, we must remember that in spite of the tremendous destructive capability of nuclear weapons, the achievement of success in a future war will be possible only through coordination in the use of all means of armed conflict. It is thus, in short, that we view the most characteristic aspects of a future war. It is quite clear that the conditions and means of waging this war will impart particular significance to its initial period, which we shall consider in more detail.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The essential quality of the initial period of a war. Today, scarcely anyone can doubt that the results of armed conflict in the initial period of a war will have a decisive significance for its whole subsequent course.

If we turn to history, we can find in past wars many examples in which, right up to the outbreak of military operations, the belligerents were working to complete the preparations necessary for the seizure of the initiative from the very beginning of the war and the consequent predetermination of the further course of the war in their favor. And, despite the fact that there were not at that time sufficiently effective means of armed combat, as a rule, the side which seized the initiative in operations achieved victory over its adversary. Let us consider some historical examples.

In the Russo-Japanese war of 1904-1905, both sides, foreseeing the inevitability of the war, undertook strenuous preparations long before its outbreak. In this, however, Japan far surpassed Russia and began the war without a formal declaration on the night of 9 February 1904 with a surprise attack on the Russian squadron at Port Arthur. The results to which this Russian procrastination in preparing for war led are well known to everyone.

The First World War was also prepared for in advance. The main states which participated in the war took every step to carry out concealed mobilization and to forestall the enemy in the deployment for and the launching of military operations. However, neither side succeeded in this. The difference in timing (v srokakh) and in the time taken to mobilize and to deploy the armed forces of the main European powers was insignificant, and both sides began military operations under relatively equal conditions. As a result neither side was able to seize the initiative in the very first days of the war and to achieve decisive successes either at the beginning or in the subsequent course of the war.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Events developed quite differently in the Second World War. Hitler's Germany, which had secretly mobilized its armed forces beforehand under the pretext of conducting maneuvers, concentrated and deployed them on the national border with Poland. The Polish command, not having correctly evaluated the military capabilities of fascist Germany, was not prepared for war. Mobilization was begun in Poland only on 29 August, and on 1 September 1939 the German fascist army invaded Poland from various directions and defeated the Polish Army decisively. In the course of three weeks the Polish Army was completely destroyed and Poland was occupied by the German fascist troops.

The German fascist army was able to achieve the same decisive results in the war against the other Western countries. Even such a country as ours needed more than a year to eliminate the consequences of the failures of the initial period of the war and to achieve a breakthrough in military operations in our favor.

Failure to evaluate the part played by the initial period of a war or the incorrect appreciation of its content and special features have led to a situation in which some countries and their armed forces have turned out to be inadequately prepared to conduct a war, have suffered huge losses, or have lost the war at its very beginning.

In the initial period of a future war the qualitative and quantitative status of modern means of armed conflict will create conditions for the achievement of incomparably greater results than has been the case in any war in the past. It should be clear to all of us that the surprise massive use of nuclear weapons can inflict huge losses in human and material resources on the armed forces and on the entire country undergoing attack, can disorganize front and rear areas, and governmental and military control, and can disrupt the systematic

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

deployment of the armed forces and the carrying out of mobilization in the country.

All this obliges us to study the initial period of a future war with care and seek out the most effective means for the conduct of armed combat during this period.

It should be noted that before the Second World War we had no properly evolved theory for the conduct of a war in its initial period. The views which prevailed at that time concerning the conduct of operations during the initial period of a war were based for the most part, on the experience of the First World War.

At that time the initial period of a war was taken to be the segment of time encompassing events from the moment of the declaration or beginning of the war until the commitment of the main body of the armed forces. It was assumed that the mobilization, concentration, and deployment of the armed forces would begin after the declaration of war of after an attack by the enemy. This was considered to be the main constituentof the initial period of a war. It was assumed that military operations would be restricted to the conduct of reconnaissance operations and to border engagements by covering troops (voyska prikrytiya).

This view of the makeup of the initial period of a war had a negative influence on the preparation of our armed forces for war, and also on the development of plans for their strategic deployment. The incorrect evaluation of the changes which had occurred in the methods used by the imperialists in preparing and unleashing a war, and also of the possible nature of military operation in the initial period, resulted in the insufficient combat preparedness of the border military districts and a delay in the shift of the national economy of our country to military production. All this cost us huge losses in people and in material resources.

The Second World War brought substantial corrections

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

in the understanding of the initial period. The mobilization and deployment of the main body of the armed forces of the aggressor countries and the switch of the economy to military production were carried out in good time, before the beginning of the war. The war began without a declaration, with a surprise attack. Thus, the basic constituent of the initial period of the last war was even then not the mobilization and deployment of the armed forces, but the conduct of active military operations from the very beginning of the war.

The development of weapons and methods of conducting armed conflict, and the nature of the preparations for a future war by the imperialist countries, give grounds for supposing that its initial period will differ considerably in its constitution from past wars and even more from former theoretical concepts.

We consider that a future war will most probably begin with a surprise attack by an aggressor employing the maximum possible quantity of nuclear weapons. In the course of this attack both sides will strive to inflict on each other by the most energetic strikes, such losses at the front and in the rear that the achievement of the immediate strategic aims of the war in the shortest period of time will be ensured as a result.

For our armed forces such aims might be the repulse of the enemy attack, the seizure of the strategic initiative, and the creation of favorable conditions for the further development of decisive military operations. In the course of achieving these aims, our armed forces will have to solve such tasks as the destruction of military and industrial targets, the disorganization of the governmental and military command of the enemy, the disruption of the strategic deployment of his armed forces, the defense of our armed forces and objectives in the rear areas of the country against nuclear weapons and other means of mass destruction, and also the occupation of . . .

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

important economic and political centers and areas in the theaters of military operations.

Thus, the following conclusion on the initial period of a future war suggests itself:

- by the initial period of a future war one must understand the period between the beginning of the outbreak of war and the achievement of their immediate strategic objectives by the forces of the first strategic echelon (troops in constant combat readiness - ground, air, antiaircraft defense, and, in the first rank, missile troops);

- the main constituent of this period will be the conduct, from the very beginning of the war, of active military operations by peacetime forces and weapons, including formations mobilized up to wartime tables of organization and equipment and units maintained in skeleton strength on ready-reserve status. All types of armed forces will take place in these operations. The leading role will be assigned to the missile troops of strategic designation.

As to the duration of the initial period itself, one must keep in mind that it cannot be determined ahead of time. Its length will depend on the time required to achieve the immediate strategic objectives of the war, on the nature of these objectives, on the conditions under which the war breaks out, on the course of deployment of the armed forces, on the results of military operations, and also on a whole series of other factors. Only one thing is clear - that the objectives of the initial period of a future war can be achieved in a considerably shorter time than has been the case in the past.

For the correct determination of the nature of military operations in the initial period of the war, and of the methods of conducting them, a knowledge of the probable enemy, constant study of his true intentions, of the grouping of his armed forces, and particularly of his means of nuclear attack, and an

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

objective evaluation of his combat capabilities are of great significance. It is quite obvious that the determination of the methods of operation of our armed forces and the effectiveness of their blows will also depend upon the timely disclosure of the true plans of the probable enemy against the countries of the Socialist Camp.

It must be said that a great deal of attention is given to the problems of a future war, and particularly to its initial period, in the armed forces of the imperialist countries. The military leaders of the aggressive blocs, headed by the United States and England, assign a decisive role to the initial period of a war, and particularly to the first operations.

In determining the methods of conducting armed combat in the initial period of the war and in the preparation of the armed forces, very great importance is attached to knowledge and consideration of the conditions in which the aggressive imperialist blocs can unleash a war against the countries of the Socialist Camp.

The combat characteristics of modern weapons, and also the practical actions of the leaders of the imperialist blocs, provide reasons for considering that the most probable method of unleashing a war against the Soviet Union will be a surprise attack from various directions with the widespread use of nuclear weapons. In this case the war will immediately become worldwide in character.

It is not excluded that war may be unleashed by the imperialists with an attack on one of the countries of the Socialist Camp. Naturally, the Soviet Union and the other countries of the Socialist Camp will be forced to enter this war, with the aim of providing assistance and defense to the friendly country which has suffered the attack. In this case, the war cannot be confined to a local conflict, but will turn into a world war.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Finally, there may also be other conditions in which the imperialists will unleash a war, conditions which will undoubtedly leave their imprint on the nature and means of operation of our armed forces. We must study all these conditions attentively so that we will be ready in good time to take effective and decisive countermeasures in any situation.

The probable enemy will take as his main objective that of depriving us of the capability of using nuclear weapons from the very beginning of the war. For this it is contemplated that strikes will be delivered throughout the whole depth of our country in order to destroy our stocks of nuclear weapons and missile-launching installations, to destroy our airfields, annihilate our bomber aircraft, and inflict decisive destruction upon our armed forces.

Simultaneously with the fulfilment of these missions, we know that it is planned to deliver strikes against our most important administrative-political and military-industrial centers, naval bases and ports, railroad junctions, and other objectives in order to disorganize the administration of the country, to disrupt the mobilization and deployment of our armed forces, and to shatter the military and economic potential of the country and the morale of the people.

For the fulfilment of these missions it is planned to bring to bear the maximum quantity of forces and means capable of using nuclear weapons, in order to inflict immediate and decisive destruction upon us and to achieve their plans for seizing the German Democratic Republic, Poland, Czechoslovakia, and Hungary, and of carrying the war to the territory of the Soviet Union.

In the imperialist countries, particularly in the NATO countries, in accordance with these aggressive plans, the buildup of armed forces and their training for war are being carried out, theaters of military operations are being equipped at an accelerated rate, reserves of material and technical resources are being

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

set up, and nuclear/missile bases are being equipped.

It is necessary to say that the rapid development of modern means of combat is constantly bringing about great qualitative changes in the armed forces, both with us and with the capitalist states. As a result, a reevaluation of the places and roles of the various types of armed forces and arms of troops in a future war are taking place, the methods of fighting a battle are changing and considerable adjustments are being made in operational plans. Many postulates of military art which appeared correct only yesterday must be reviewed and decided upon completely anew today. In this connection, we should like to recall the statements of the Chief of the General Staff, Marshal of the Soviet Union M.V. Zakharov. Speaking before the students of the Academy of the General Staff at the beginning of the present academic year, he stated that we must all watch intently the changes taking place in the armed forces of the probable enemy, investigate everything new searchingly, summarize it intelligently, and draw the appropriate conclusions for ourselves.

The combat readiness of the armed forces. The successful attainment of the strategic objectives of the initial period of a war is possible only on condition that the armed forces and the country as a whole are comprehensively prepared to conduct a war against a strong enemy. We must always remember the lessons of the past war, which show that the errors and miscalculations which we permitted in preparing the armed forces and in considering the possibilities of a war with fascist Germany had a drastic effect on our conduct of military operations, and put our country in a most difficult position.

The consequence of these miscalculations was that our armed forces were not brought to the necessary state of combat readiness in time and that we began combat operations in a disorganized fashion, as a result of which we suffered large losses. It must be said outright that under present circumstances such mistakes could have catastrophic consequences.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

This is why the chief requirement for all the armed forces at the present time is the maintenance of a high and constant state of combat readiness. As we know, in the orders and directives of the Ministry of Defense on combat and operational readiness, the chief task which is set before our armed forces each year is to be in constant combat readiness in order to disrupt an attack by the enemy and to initiate immediate and active combat operations with the aim of seizing the strategic initiative at the very beginning of a war.

It is true, we admit, that a period of threat (ugrozhayemyy period) may precede the unleashing of a war by the enemy. However, one must not under any circumstances base one's calculations on the possibility of carrying out all the measures involved in bringing the armed forces to a state of combat readiness during this particular period. The imperialists may attempt to use their present means of attack completely unexpectedly, and they have the complete capability to do this. Therefore, in order not to allow oneself to be caught unawares, one should orient oneself on the absence of a period of threat or on one of extremely short duration, counted perhaps only in hours.

Justification for the institution of a threat situation (ugrozhayemoye polozheniye) in the country may be a sharp aggravation of the international situation or the receipt of reliable information on the clear threat of an outbreak of war. This period must be used to the maximum for bringing the armed forces to such a state of combat readiness as will permit them to begin combat operations immediately.

For this, all the measures to be carried out in the period of emergency by each sub unit, unit, and large unit and by each headquarters and establishment must be worked out and planned ahead of time. But this is not enough. All steps must be taken to ensure that the projected measures are executed in the shortest period of time with the maintenance of a high degree of organization and orderliness. For this, already

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

in peacetime, a situation must be achieved in which all the personnel of the armed forces know and can carry out accurately the responsibilities with which they will be entrusted in the period of threat.

It is not necessary to list all the measures which can be carried out in the period of threat. In each sub unit, unit, large unit, headquarters, or establishment they will be different. We will cite just the main ones.

First of all, the maximum speed in delivering signals and instructions to units and large units concerning the introduction of the threat situation must be ensured. For this all rapid means (bystrodeystvuyushchiy) of communications will be employed, observing secrecy precautions for the transmission and a safeguarding of military secrets.

With the introduction of the threat situation, the activity of all types of intelligence must be increased immediately with the aim of discovering the enemy's direct preparations for an attack, changes in the grouping of his forces and means, particularly of his means of delivering a nuclear attack, the possible intentions and the timing of his operations, and also other information peculiar to a particular axis or theater of military operations.

In organizing reconnaissance one must take into consideration that with the changes in the character of a war and with the introduction into the armed forces of means of mass destruction, reconnaissance tasks and the methods by which these can be accomplished have become considerably more complicated. Errors committed in this sphere can have an immediate and most drastic effect upon the conduct of military operations.

Upon the receipt of a signal or order about increasing readiness, all armed forces are brought to a state of complete combat readiness.

The chief concern of the command at all levels

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and headquarters during the period of threat must be the protection of troops from the nuclear weapons of the enemy. For this purpose it is necessary to foresee and to organize the withdrawal of troops, aviation, and the fleet from their permanent dispositions (mesto dislokatsii) to new areas which have been prepared in advance, at the same time bringing them to a heightened state of readiness. This applies particularly to the troops, forces, and weapons of border military districts and fleets, whose disposition the enemy has more opportunities of discovering.

In some cases, troops, forces, and weapons of the border military districts and fleets will immediately occupy the areas and positions assigned to them with the view of going into action, directly in accordance with plans which have been worked out beforehand.

The protection of stocks of material and technical supplies against destruction by the nuclear weapons of the enemy is a no less important measure, to which particular attention must be given at all times, and particularly during a period of threat. There is no doubt that the appropriate organization to protect material stocks will be already envisaged during peacetime. However, with the introduction of a threat situation steps must be taken, where necessary, to disperse them further and to organize the transport called for by the plans and in order to supplement the stocks of the troops or to establish stocks in the directions (napravleniye) where military operations are forthcoming.

One should not exclude the possibility of taking steps during the period of threat toward the partial mobilization and deployment of some part of the forces, particularly from the personnel of the ground troops, and also toward the conversion of individual branches of industry to war production. However, it must be borne in mind that this must be done with the observance of extraordinary measures of caution and secrecy. We should not rely on the possibility of conducting widespread measures for mobilization during the period of threat. The deployment of the armed forces and their concentratior

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

in theaters of military operations will be carried out mainly from the beginning of the war and under very complex conditions. Here, the problem of military transport will be very critical.

It must be taken into consideration that at the beginning of a war the operational movement of troops and the movement of material and technical supplies will be conducted on a tremendous scale. At the same time, the enemy will try to break up the operation of our communication lines by nuclear strikes and to disrupt this movement. The possibility cannot be excluded that, as a result of nuclear strikes on road junctions, bridges, and other vulnerable points and objectives, the main rail and highway arteries in various directions may be put out of commission for a lengthy period of time, which will seriously complicate the deployment and concentration of our armed forces.

The solution of this problem must lie in three courses. First, it is necessary to envisage and to organize the combined use of all types of transport: railroad, highway, air, and water, to achieve their complete interchangeability, and also to envisage broad mobility of the reserves of all transport facilities.

Secondly, we must achieve the maximum viability of our communication lines under the conditions of a nuclear war. To this end the reliable antiaircraft defense of communications must be organized. In doing this, particular attention must be paid to the protection of the more vulnerable points along the lines of communication; against strikes by the enemy transloading areas, railroad stations, highway and rail junctions, bridges, tunnels, viaducts, and other structures. To ensure the viability of communication lines, measures for combating enemy paratroops and diversionary groups must be worked out in good time.

Thirdly, it is necessary to provide for the organization and execution of rapid repair and restoration of portions of the lines of communication which have been destroyed, and for the construction of

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

new sections of railroads and highways, bridges, bypasses, and the laying of pipelines. To carry out these large and labor-consuming tasks, construction and repair units, railroad troops, the construction organizations of the transport ministries, sovnarkhozes, and also troops and the local population can be enlisted. The successful carrying-out of reconstruction and construction operations on communication lines will be assisted by the timely creation of stocks of building materials and of prefabricated bridging construction.

For defense against the means of mass destruction and for the elimination of the effects of nuclear strikes, commanding officers and headquarters will organize measures for antiatomic, antichemical warfare and antibacteriological defense in the sectors or areas of action of their formations and also along the lines of communication, and will assign the requisite forces and resources.

All these measures for assuring the viability of communication lines are planned in advance.

In speaking of the combat readiness of our armed forces, it must be kept in mind that by this we do not mean just the ability of sub units, units, and large units to assembly quickly at the alert signal (po trevoge) and to occupy the areas assigned to them. This is only one of the elements of the combat readiness of troops, forces, and weapons, and it is very important. But it is not all-important. The combat readiness of troops is made up of very many elements, the fundamental one of which is combat coordination (slazhennost) and constant readiness to conduct military operations during the mass employment of all modern means of combat, to fulfil any task which may be assigned to the unit or large unit at the beginning of a war. Units or large units which , although they assembly quickly at the alert signal, are not capable of executing a combat mission, cannot be considered combat ready.

The fundamentals of combat readiness are: a high degree of field training of the troops; having combat

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

equipment in excellent condition and being able to use it; well-organized control of troops and their readiness for rapid assembly; the presence of stocks of the material and technical supplies necessary for the supply of the troops in case they are alerted, and, in addition, for internal military districts, readiness to mobilize and to be transported or to carry out marches over long distances.

The high state of readiness of the armed forces for the conduct of operations in the initial period of a war will depend to a great degree on the level of training of commanders, commanding officers, and staffs, and on their ability to direct troops confidently and firmly under the complex conditions of the situation.

Another of the most important conditions ensuring the readiness of our armed forces for the successful conduct of military operations in the initial period of a war is the timely preparation of the territory of the country and of the probable theaters of military operations for a future war. Modern powerful, long-range means of destruction greatly widen the borders of the theaters and present new demands for their preparation (oborudovaniye).

What are the minimum necessary measures which must be taken already, in peacetime, to equip and prepare theaters of military operations?

The basic measures for the preparation of theaters of military operations can be given as follows: the development of lines of communication and the ensuring of their reliability and viability under conditions of the mass use of nuclear weapons; the construction of launch sites for missiles; the construction of airfields; the development of a communications network; the creation of a unified radar and radionavigation system; the equipment of bases and depots for the storage of materiel; the camouflaging of the most important targets in order to exclude their detection by any type of reconnaissance,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

including technical means.

Such, in short, are the requirements for the combat readiness of the armed forces and the most important measures to be taken to ensure it.

The nature and means of conducting military operations in the initial period of a war. The nature of, and means for, conducting military operations in the initial period of a war will be determined by the situation in which the war may break out. However, it can be said with complete confidence that under all circumstances massed nuclear/missile strikes will form the basis of military operations. The reserves of nuclear weapons accumulated during peacetime will be used immediately to the maximum possible degree to inflict decisive damage on the enemy in order to force him to capitulate or to create a situation of complete chaos in the country, and to make the development of active military operations and the carrying out of mobilization measures as difficult as possible for the enemy.

As has already been said, the most probable method by which the imperialists will unleash a war against the Soviet Union will be a surprise nuclear/missile attack. The unleashing of a war in this manner creates exceedingly complicated conditions for us, and we must prepare our armed forces for this before all else.

The chief task of the armed forces in the event of such an attack will consist of preventing mass nuclear strikes by the enemy, of instantly delivering crushing strikes by nuclear weapons, and of initiating vigorous military operations by all types of armed forces. In other words, we must disrupt the attack of the enemy and immediately seize the strategic initiative with all the forces and means at our disposal.

Thus, by the disruption of the attack of the enemy one must understand the sum total of military operations conducted by all the armed forces. The

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

fundamental basis of the execution of this task will consist of nuclear strikes by the strategic missile forces, by the missile units and large units of the ground troops, and also by aircraft and missile submarines.

Successful operations by the missile troops, and, particularly, their first strikes, will determine the results of the armed conflict in the initial period of the war, and also during the course of its further development. Missile forces are the forces of a future war. It is for this reason that their development is now given such great attention.

A no-less-important role in disrupting the attack of the enemy will be played by the forces of the PVO of the country and by the antiaircraft forces and weapons of the ground troops and the navy. They must fulfil their task of destroying the missiles and aircraft of the enemy in the air and of thus preventing him from striking the vitally important objectives of our country and armed forces.

We should also not minimize the role and significance of our ground troops in the disruption of the enemy's attack. Having as their armament nuclear weapons and other modern means of armed combat, and possessing a high degree of mobility and maneuverability, they are capable, by swift actions, of inflicting decisive damage on the troop concentrations of the enemy, of moving rapidly deep into his territory, of seizing vitally important areas of the country, and thus of making more difficult the basing of the missiles, aircraft, and navy of the enemy, of disrupting the conduct of mobilization measures, and of depriving him of the ability to make up the losses which he has suffered.

The role of our air forces in disrupting the attack of the enemy will consist mainly of supporting the combat operations of the ground troops and fleet, and also in conducting reconnaissance. Long-range aircraft will be used to make strikes on targets located deep in the theaters of military operations

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

which are weakly protected by antiaircraft defenses.

The efforts of the navy and particularly of its missile submarines and aircraft, disrupting the attack of the enemy will be directed primarily toward combating the carrier strike large units (soyedineniye) of the enemy and his missile submarines and surface vessles.

In speaking of the disruption of a surprise attack by the enemy, the decisive significance of the first blow, which must be the most powerful, should be particularly stressed. The industrial and economic centers of enemy countries, the missile, aircraft, and naval bases of the enemy, his stockpiles of nuclear weapons, aircraft, nuclear-powered submarines, missile vessels, and aircraft carriers, the most important groupings of his ground troops, radar facilities, and other objectives will be subjected to its destructive action.

A first strike using massed nuclear weapons delivered at the right time can considerably weaken the strikes of the enemy, can paralyze his operations for a certain time, and under favorable conditions, can force him to cease active military operations. The success of such a strike will be determined by the degree of combat readiness of all the forces and weapons used to deliver it, by the validity of information on the objectives to be destroyed, by their proper selection, and by the skilful use of nuclear weapons to fulfil the basic tasks.

Of all of the tasks of the initial period of a war, the two most important, which will be carried out by the combined efforts of all types of armed forces and with all possible means, must be singled out. These are the fight against means of nuclear attack and the disruption of the deep rear of the enemy.

The mass employment of missiles with nuclear charges (zaryad), particularly at the beginning of a war, may very seriously complicate the activity

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

of a country and of its armed forces. Therefore, the fight against means of nuclear attack, and in the first place against missiles, now assumes significance of the first order.

This fight must be conducted in a systematic manner, both in the theaters of military operations and in the deep rear of the enemy, using the combat capabilities of all types of armed forces. The organization of the fight against means of nuclear attack will be one of the most important tasks of any operation. The chief role in its fulfilment will belong to the missile troops, since the achievement of decisive results in the fight against means of nuclear attack is possible only when nuclear weapons are used on a large scale.

One of the requisites for the fight against means of nuclear attack will be the constant conduct of reconnaissance, the timely preparation of forces and weapons targeted on definite objectives, and decisiveness in the conduct of military operations. The protection of one's own means of nuclear attack against the strikes of the enemy will also have great significance for the success of this fight. This is achieved by a reliably organized system of antiaircraft defense, and also by dispersing and concealing the disposition of missile launch sites, aircraft, and depots and assembly bases for nuclear weapons.

The complexity of the fight against means of nuclear attack results from the fact that the anti-air means for the destruction of ballistic missiles (ballisticheskaya raketa) in flight are still in the developmental stage. The destruction in the air of cruise missiles (krylataya raketa) and also of modern, high-speed, high-altitude aircraft, especially during their mass use, presents a well-known difficulty. Therefore, the basic method of fighting means of nuclear attack, at least in the near future, is their destruction on the ground (on launch sites, bases, airfields, depots, and at places of production) in conjunction with their destruction in the air. In the fight against missiles and aircraft of the enemy's

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(e)(4)

navy, the greatest results can be achieved by inflicting strikes on aircraft carriers, and on surface and submarine missile-carrying vessels at sea and at bases.

The solution of the task of fighting means of nuclear attack is inseparably bound up with another task -- the disruption of the enemy's rear. In a future war, the objectives in the enemy's deep rear will immediately be under direct strikes by the means of mass destruction, and its disruption will be the most important task of our armed forces from the very beginning of the war. Enormous destruction and property and personnel losses resulting from the mass use of nuclear weapons will result in the crippling of governmental and military control, in the upheaval of the military and economic power of hostile states, in the destruction of transportation systems, in reduction of the combat effectiveness of the enemy's armed forces, and in the demoralization of the population.

The disruption of the enemy's deep rear will require the performance of a number of important tasks. In the initial period of a war such tasks can be: the annihilation of reserves of nuclear weapons and missiles, the destruction of industrial objectives producing these weapons and also of the most important economic, administrative-political, and scientific-technical centers, and the annihilation of national reserves of finished military-industrial products. The successful performance of these tasks can exercise a serious influence on the course of the war at its very beginning.

Missile weapons, and in the first place strategic missiles, are the main means of delivering strikes against objectives in the enemy's deep rear. Operational-tactical missiles and long-range and front aircraft (aviatsiya) will be used to deliver strikes against objectives in the enemy's rear which lie within the zone of their range, against naval forces, especially missile submarines, for the destruction of sea and

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

ocean communication lines with the aim of isolating hostile nations from the theaters of military operations and from sources of raw material. Ground troops can also fulfil tasks connected with the destruction of enemy objectives in his immediate rear by the delivery of strikes by missiles and aircraft. Airborne troops also can take an active part in the performance of this task.

Military operations concerned with the disruption of the enemy's deep rear are planned beforehand on the armed forces level and will be carried out under the direction of the Supreme High Command. Operations in the initial period of a war are planned in the utmost detail, especially in connection with the infliction of the first strike.

The feature distinguishing military operations in the initial period of a war from those of the very beginning of the war is their wide range. Both sides will strive to inflict mass strikes with nuclear weapons, not only on the troops in the theaters of military operations, but also, as has already been noted, on the deep rear, in order to ensure the attainment of the immediate strategic goals in the shortest period of time, to capture the initiative more quickly, and to ensure its firm retention.

Immediately after the first missile and aviation strike, or during the course of this strike, groupings of ground troops will turn to the offensive in the main directions. On those sectors of the front where a situation which is unfavorable for the turning of troops to the offensive takes shape at the beginning of the war, they will conduct defensive operations in order to prevent a breakthrough into the depth of our territory by the enemy groupings, to inflict destruction on them, and, with the approach of the reserves, to turn to the offensive.

The navy will develop active combat operations in the naval theaters, where the principal task will be to inflict destruction on the enemy's navy at sea and at its bases.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The troops of antiaircraft defense of the country will conduct combat operations for the destruction of the aircraft and the annihilation of enemy missiles in the air.

Thus, combat operations at the beginning of the war will represent a system of operations which are interrelated and directed against a common goal by all types of armed forces, and which are planned and coordinated with one another even during peacetime. The appropriate forces and weapons are earmarked beforehand and the supplies of material and technical equipment necessary for the conduct of these operations are also provided for.Corrections are made, when necessary, in the plans which have been worked out, in connection with the changes which have taken place in military districts, groups of troops, fleets, and the armed forces as a whole.

Let us dwell on the characteristics of the combat operations of the various types of armed forces in the initial period of a war.

As has already been stated, the decisive role in performing the tasks of the initial period of a war belongs to the missile troops of strategic designation. They will deliver massed nuclear/missile strikes for the fulfilment of strategic tasks in support of armed combat as a whole. The objectives of nuclear/missile strikes are industrial and administrative-political centers, aircraft, missile, and naval bases, nuclear ammunition at storage and assembly points, and the most important groupings of the armed forces.

Nuclear/missile strikes can also be delivered in support of armed combat in the theater of military operations with the aim of annihilating the basic groupings of enemy armed forces, of destroying and annihilating important objectives, and of breaking up the concentration of his forces and weapons in the theater. The successful performance of these tasks will create favorable conditions for the conduct of military operations in a given theater. Here the timely exploitation of the results of nuclear/missile 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

strikes by other types of armed forces will have important significance. Massed nuclear/missile strikes and the coordinated efforts of all types of armed forces should bring about the decisive destruction of the enemy in the initial period of the war and the achievement of the immediate strategic aims.

At the very beginning of a war, the enemy will also strive to achieve his aims through the mass use of nuclear weapons. Therefore, military operations in defense of the country and of the groupings of armed forces, against enemy nuclear strikes, take on paramount significance for us. This task will be performed mainly by the troops of the PVO of the Country. It is precisely for this that they are primarily intended.

Military operations in defense of the country against enemy nuclear strikes in the initial period of a war will be conducted in accordance with plans worked out earlier on the basis of a system of anti-aircraft defense set up during peacetime. This system must always be ready to repel surprise strikes by enemy means of air attack.

With the introduction of a threat situation or with the receipt of the first information concerning preparation of an air attack by the enemy the entire system of antiaircraft defense is brought to increased combat readiness. Simultaneously, a partial regrouping of forces and weapons for the reinforcement of the defense of the most important axes, areas, or objectives can be executed if necessary, and fighter aircraft can be dispersed. Part of the radar posts are moved to alternate positions. Command posts and control posts (punkt navedeniya) are brought to complete readiness to control the troops.

The repulse of the first enemy mass aviation and missile strike will be carried out by the maximum possible quantity of forces and weapons of the troops of the PVO of the Country, fronts, and fleets. In the first place, the duty means (dezhurnoye sredstvo) of antiaircraft defense will begin to function. Their

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

efforts will be intensified immediately by the large units and units of antiaircraft missile troops, fighter aircraft, and antiaircraft artillery which have been brought to combat readiness.

After the repulse of the enemy's first mass strike, the entire system of antiaircraft defense may immediately be made ready to repel subsequent strikes. In case of need, the movement of antiaircraft weapons and aviation will take place in reinforcement of the defense of important areas and objectives, the supplies of materiel are replenished and the coordination procedure is spelled out.

Simultaneously with the delivery of nuclear/missile strikes against the enemy decisive military operations will be developed in the ground theaters in the initial period of a war. In the course of these operations, the following basic tasks can be performed: the destruction of enemy groupings, the capture of vitally important territories and areas where the means of armed combat are based, and also the holding of the territory of our own country and of territory taken in the course of the war. The essence and paramount task of armed combat in the ground theaters is the destruction of operational-tactical attack weapons.

Ground troops and the missile large units and units included in their complements, aircraft, and airborne troops are the main force in the fulfilment of tasks in land theaters. Long-range aircraft and large units of the troops of the PVO of the Country near the front (prifrontovoy) can also be used to participate in the performance of these tasks. In a number of cases the missile troops of the Supreme High Command will be used for the performance of strategic tasks.

Military operations in ground theaters will be conducted mainly in the form of offensive operations by ground troops with the participation of other types of armed forces. Defense can be used as a temporary form of combat operations only in

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

separate directions of the secondary theaters or in theaters with special terrain conditions. In some cases, the defense of large units and armies will also be used in the main theaters, but as a rule these will be actions forced upon them in the course of offensive operations.

The operations of the missile troops, the delivery of nuclear/missile strikes against the enemy, and the immediate exploitation of their results by advancing troops must be made the foundation of operations by ground troops. The most important aims of the offensive operations of the initial period of a war may be the destruction of the enemy troops deployed at the beginning of the war or concentrating in groupings, and also of the strategic reserves brought into battle in the course of the operation; the disruption of mobilization and of the concentration and buildup of armed forces in the theater of military operations; the seizure of important economic and political centers, and also of areas of operational or strategic significance. The specific aims of an operation will be determined in accordance with the situation which has developed.

The aims which have been mentioned can be achieved through the execution of several successive operations throughout the depth of a front or a group of fronts, as a result of which favorable conditions should be created for the future successful conduct of armed combat. The first offensive operations will have a decisive significance in the destruction of enemy troops, in the seizure of the initiative, and in the attainment of the immediate strategic aims of the initial period of a war.

These operations can begin under various conditions. In the main direction of the basic theaters of military operations, we will have to conduct offensive operations against an enemy who has prepared for aggressive operations strongly and in good time. In a number of directions, the operations will often begin with meeting engagements, but they can also be conducted

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

against an enemy who has gone over to the defensive hastily.

It is also necessary to take into account conditions in which the enemy is able to drive wedges into our territory in several directions. In such a case, a very complex situation can be created in which the switch of our troops to the offensive will be preceded by the conduct of defensive operations.

With all the diversity of conditions governing the conduct of the initial offensive operations, everything will be tense in character and will be marked by a fierce struggle to seize the initiative. Combat operations will be accompanied by the mass use of nuclear weapons by both sides, with the aim of achieving maximum results at the very beginning of the war. This requires skilful and immediate exploitation by our troops of the results of mass strikes by nuclear weapons for the swift development of the offensive. Together with this, well-conceived organization of the system of measures to reduce the effective action of the enemy nuclear weapons and to safeguard our own troops is necessary.

The first offensive operations will be started, as a rule, by those forces of border districts and groups of troops which can be brought to complete combat readiness right from the beginning of the war. A shortage of these forces will necessitate their particularly skilful use in the main directions and the employment of weapons of mass destruction, in the first place, against objectives whose destruction will best promote the advance of the troops and the execution of a skilful maneuver, with the aim of a rapid movement into the depth of the enemy's positions. The reinforcement of fighting (deystvuyushchiy) fronts will be carried out in the course of the operation with the forces and weapons arriving from the interior of the country, and also through maneuver from other axes.

The mobile character of combat operations in the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

initial period of a war makes necessary an operational troop formation which will assist their rapid change of formation, the transfer of efforts from one direction to another, and the development of the offensive where it will achieve the greatest success. The transfer of efforts from one direction to another will be achieved by redirecting the strikes of nuclear/missile-weapons in conjunction with the maneuver of large units of ground troops.

The operational formation of the front in the first offensive operations will most frequently be of a single echelon. In this case, at the beginning of the operation it is necessary to have strong reserves under the orders of the front commander. The second echelon, as a rule, will be created in the course of the offensive with the arrival of new formations. Part of the forces in the complement of the troops of a front can be deployed along the border in the initial period of a war to repel possible enemy strikes, and to support the build-up and switch to the offensive of the front strike groupings (udarnaya gruppirovka).

In spite of the fact that the first offensive operations will be conducted by comparatively limited forces, they will have great spatial scope.

The absence of an enemy defense system prepared earlier will permit the first offensive operations at the beginning of the war to be carried to a great depth. In the main directions, the depth of a front operation can reach 500 to 600 kilometers with a width of offensive zone up to 400 kilometers, and considerably more in mountain and desert areas. The destruction of the basic enemy groupings and the seizure of his territory to such a depth will facilitate the achievement of the strategic tasks of the initial period of the war in the shortest period of time. The performance of these tasks will require a high rate of advance by the troops. Effective use of the weapons of mass destruction and the high mobility of the groung troops will permit the delivery of strikes in depth against the enemy and will bring about an advance at high speeds. Under modern conditions, an offensive can attain an average daily speed of 100 kilometers and more.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The distinctive feature of the first offensive operations lies in the fact that at their outset the main forces of both sides will not come into contact with one another, and that therefore the offensive will most frequently develop from the march. The front's first echelon troops, which can be deployed in departure areas or areas of concentration before the beginning of military operations, must be at such a distance that they can be moved quickly to the national frontier and go over to the offensive, exploiting the results of strikes by nuclear weapons.

It can also be that the troops moving up to the border from areas of permanent disposition will begin combat operations on the basis of a brief order or signal from the senior commander with reference to one of the operational variants envisaged by the plan.

Under conditions when the enemy forestalls us in the deployment and in the delivery of strikes from the air and by land groupings, the front's troops must inflict destruction with strong counterstrikes against the invading enemy and go over to a decisive offensive which will be preceded by powerful strikes by missiles, aviation, and artillery against the enemy's groupings and against his missile-launching sites, aviation, and reserves. After the infliction of destruction on the enemy's basic grouping, the front's troops must develop the offensive in depth unceasingly, with the aim of utterly destroying the enemy's troops and of fulfilling the assigned missions.

The offensive operations of the initial period of a war can be conducted in various ways. In a case when the enemy's defense is not prepared, his groupings of troops are dispersed, and his large reserves are located in the depth, it is not advisable to deliver swift, deep strikes in several directions. During this, it is necessary to concentrate the main efforts in the direction where the maximum results can be obtained in the shortest period of time and with the smallest losses. Such a method of operation

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

ensures the greatest degree of diffusion of the enemy's front, the dispersion of his efforts, the destruction by units of the approaching reserves, and the seizure of important areas and objectives in the enemy's territory in great depth. During this, swift penetrations by strike groupings to the greatest possible depth will have particularly important significance.

Such groupings, exploiting to the utmost the results of nuclear strikes and avoiding involvement in prolonged engagements with the enemy remaining in the rear and on the flanks, must destroy the large enemy reserves, capture the areas where nuclear delivery means are based, disrupt communications and control, seize vitally important areas and objectives, and thwart the deployment by the enemy of his armed forces.

Other ways of conducting offensive operations can also be employed, for example, a strike in two directions, the encirclement and annihilation of large enemy groupings with the simultaneous development of an offensive in depth, and a strike in one direction. The methods and ways of conducting an offensive operation must always be determined by the particular conditions of the situation.

Together with the conduct of offensive operations in the initial period of a war, defensive operations can be carried out in separate directions or in secondary theaters of military operations.

These defensive operations, which we are considering as a temporary type of combat operation, can be aimed at disrupting the enemy's offensive, preventing his intrusion into our territory, inflicting the greatest possible losses on him, gaining time for the concentration and deployment of troops, and thus create favorable conditions for a switch to the offensive.

[redacted] 1.3(a)(4

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Defensive operations can also be conducted in the course of a general offensive which has already begun. In this case, the defense will be conducted on separate sectors of the front by units and large units, and possibly by individual armies and will be conducted in support of the offensive.

The planning and preparation of a first defensive operation in those directions or theaters where, at the beginning of the war, the execution of extensive offensive operations is not proposed, are carried out during peacetime. The most probable variants of combat operations, subject to the possible conditions under which the operation can begin, are outlined in the plan. Besides the usual measures, the organization of cover for troop deployment in the border zone is provided for. It is quite clear that not all the conditions of a situation can be considered in the plan. On the eve of the war or at the beginning of military operations, therefore, it can be made more precise.

The defense will be built up and conducted differently from the last war. There will not be the defensive lines and zones which were set up in the past. The basis of defense must not be the creation of a solid front, but nuclear/missile strikes, the extensive use of fire maneuver and of maneuver by forces and weapons in combination with the holding of important areas and sectors and the use of various obstacles.

Those forces and weapons which will be in the border military districts at the beginning of a war will be used to execute the first defensive operations of the initial period of a war. The intensification of efforts in the course of the operation will be conducted, in the first place, by the maneuver of forces and weapons from other directions. It is advisable to use the troops arriving from internal districts mainly for the final destruction of the enemy in the course of the offensive.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The operations of the defending troops will be distinguished by great intensity and high aggressiveness. From the very beginning of military operations, both sides will strive to achieve decisive results by nuclear weapons strikes. In a defensive operation in the initial period of a war, success can be attained only by the skillful concentration of basic efforts in directions where the enemy's offensive is expected, by mass nuclear strikes against his troops, by the means of nuclear attack, and by the extensive use of maneuver.

This success will also depend in large measure on the outcome of combat with an enemy grouping breaking into the positions of the defending troops. The destruction of such a grouping must be carried out by decisive counterstrikes.

In the first defensive operations, the troop grouping which will be used to deliver the counterstrike will be assembled earlier, but the counterstrike itself will most often be inflicted from the march. It must begin with strikes by missiles, aviation, and artillery using nuclear weapons against the main enemy grouping. Following this, the troops of the counterstrike grouping go over to the offensive. These troops must operate decisively and advance at high speeds until the complete destruction of the invading enemy grouping is achieved.

We will briefly consider air operations in the initial period of a war.

As is known, the development of missile equipment and its introduction into all types of armed forces, and also the significant increase in the effectiveness of modern weapons of antiaircraft defense, have caused a decrease in the role of the air forces, and especially of bomber aviation in armed combat. We are at present going through the process of replacing the long-range and front bomber aviation with strategic and operational-tactical missiles; however, we consider that aviation will keep its significance for some time yet.

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Long-range aviation will have to carry out tasks concerned mainly with the destruction of objectives which are weakly protected by antiaircraft weapons, and front aviation will be concerned with the support of ground troops and with ensuring that long-range aviation successfully overcomes enemy antiaircraft defense in the area in the vicinity of the front (prifrontovaya polosa) by neutralizing control points, the radar network, and the active means of the PVO.

One of the conditions of success of an operation in the initial period of a war is that heightened combat readiness be attained rapidly, and also that timely escape from an enemy strike can be achieved by the takeoff of the aircraft or by their transfer to other airfields. As a rule, the escape of bomber aircraft from an enemy strike must be completed by the delivery of strikes against his objectives, irrespective of the time of day.

The basic method of operation by bomber aircraft is the delivery of successive, massed strikes. At the beginning of the first strike, intensive air and radio-technical reconnaissance is conducted with the aim of obtaining information for subsequent strikes by missiles and aircraft, and also of determining the degree of destruction of the enemy objectives. Strikes delivered subsequently take into account the results of previous operations and newly arising tasks.

Naval operations. In the initial period of a war the navy will conduct operations in the first place with the aim of destroying the enemy's missile submarines, of inflicting destruction on his carrier strike large units (soyedineniye), also of disrupting sea and ocean transport.

Naval operations will be conducted primarily by the forces of large units of submarines and naval aircraft with the participation in some cases of large units and units of strategic missile troops and long-range aviation.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The first naval operations will have particularly important significance in the performance of tasks in the initial period of a war. Advance and systematic study of the combat composition of the enemy's navy and of those of his objectives which it is intended should be hit during the delivery of the first strike at the very beginning of the war will significantly influence their success.

This strike must be carried out by naval forces in the minimum amount of time after the receipt of a signal regarding one of the earlier planned variants. It is delivered against objectives whose destruction would lead to the frustration of the enemy's nuclear strikes from the sea and the significant weakening of his navy. For the navy, in the first place, such objectives will be missile submarines and the carrier strike large units of the enemy and also his naval bases and most important ports, with the warships and transports which are there.

The maximum possible quantity of forces and weapons, with mass use of nuclear warheads, is used for the delivery of the first strike. Such a strike against enemy objectives in remote areas will be delivered by strategic missile large units, by submarines, by long-range naval aviation, and also by large units of long-range aviation assigned to the support of the navy. The destruction of enemy coastal objectives will be carried out, as a rule, by missile troops, and in some cases this task can be assigned to missile submarines.

For the performance of tasks in closed naval theaters and in the closest areas of open seas, surface vessels armed with missile weapons and mine-torpedo aircraft will also be used.

In order to keep the enemy under tension during intervals between mass strikes, it is advisable to conduct combat operations by small groups of submarines and aviation, and also to make methodical missile launchings using various means of destruction.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The successes attained as a result of previous military operations must be consolidated by followup operations. Their aims will depend upon the success of the first naval operations and on the further tasks of armed combat at sea.

In speaking of armed combat in the initial period of a war, it is necessary to emphasize that none of the types of military activities or of operations which will be conducted in this period can be examined in isolation from one another. All of them will be coordinated according to target, time, and place and will be united by the single plan and direction of the Supreme High Command.

Active and decisive operations on the fronts and in the deep rear of the enemy in the course of the operations during the initial period of a war must lead to the undermining of the enemy's ability to withstand the disorganization of his rear, the seizure of the initiative by us, and the attainment of the immediate strategic aims of the war.

The subsequent course of the war will depend to a large extent upon the results of armed combat in this period.

We believe in the inevitability of our victory, the complete destruction of the aggressive imperialist states, and the downfall of the entire world system of capitalism. But this victory will not come into being by itself. We must prepare ourselves and our glorious armed forces for it tirelessly and with all our power.

MEMORANDUM FOR THE FECCFD [redacted] 1.3(a)(4)

TO: CSR/9

Jan 11, 1961 1962

SUBJECT: [redacted] 1.3(a)(4)

1. The episode reported in [redacted] letter of 22 December, when [redacted] left alone for a few minutes in BUZINOV's office in the midst of a pile of secret papers, whipped out his Minox and tried to photograph VARENTSOV's "Theses", is but the latest and most dramatic illustration of a problem which has been troubling everyone connected with the case here for some time: the collossal and ever increasing risks that we are permitting [redacted] to take in the pursuit and transmittal of documentary intelligence. Another good illustration is the 420 page manual on atomic weapons which we recently requested [redacted] to obtain, and which now looks as if it will be of no more than marginal interest. Our frequent admonitions to [redacted] to be careful, to think first and foremost of his own security, to meet [redacted] less often, etc.,etc, — in the context of our simultaneous requests to ~~xxxxx~~ retake p. 18 of this, pp. 11-13-15 of that, and pp. 1-420 of the other — are of a "stop it, I have it" nature, and have clearly been interpreted by [redacted] in this vein. 1.3(a)(4)

2. It is clear that the great dangers to the operation in its present stage lie in the frequent meetings with [redacted] and [redacted] photographic endeavours, the two being of course largely interdependent. It should be sufficient to note that [redacted] has had 10 meetingswith [redacted] in the past ~~12~~ 11 (Oct 20 to Jan 5 exclusive) weeks, and that she has gone to the meeting site on several other occasions. In this same period, [redacted] has passed 27 rolls of film. These risks are not a constant factor in our operational equation; they increase geometrically with the regularity and frequency of the meetings and the amount of material photographed and passed. 1.3(a)(4)

3. It should be noted that just because these risks were justified at one stage in the operation, does not mean that they are necessary now. The following factors deserve consideration:

a) the translation backlog;

b) the evaluation backlog: consumers have not had a chance to properly digest the documents already provided.(It seems to me that it's entirely possible that we have already reached a point of diminishing returns on some of the articles and manuals.)

c) the improvement in [redacted] own reporting, which is increasingly timely, specific and well-sourced. 1.3(a)(4)

In the light of these factors,it seems to me that we can well afford to call a halt on photography for a few motnhs ~~xxxxxxxxx~~ this will allow [redacted] to "cool off" and will enable us to get caught up on the backlog and to take better stock of what we have. 1.3(a)(4)

APPROVED FOR RELEASE

[redacted] 1.3(a)(4)

4. Everything else appears to be shipshape, and future prospects are brighter than ever, what with [redacted] rise in professional stature and the avenues of access opening up before him (e.g. KOROLENKO). All the more reason to examine carefully at this time whether or not we are justified in jeopardizing this unique source in the interests of acquiring more military manuals (in this connection, the record shows clearly that [redacted] himself is not a good judge of what risks he can and should take). 1.3(a)(4) 1.3(a)(4)

5. It is recommended that [redacted] be immediately instructed to suspend all documentary photography until further notice, and to concentrate on his own reporting. It is further recommended that we reduce the scheduled meetings with [redacted] to once every two weeks. 1.3(a)(4)

SUBJECT : [redacted] MILITARY THOUGHT: "The Nature of Modern Warfare", by Colonel-General A. Babadzhanyan.

DATE OF INFO : January 1961

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Nature of Modern Warfare", written by Colonel-General A. Babadzhanyan.

This article appeared in the 1961 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. This issue was consigned to the printer on 13 January 1961.

Headquarters Comment: The article by General Gastilovich which is cited below was disseminated as [redacted] General Tolkonyuk's will soon be published as [redacted] General Baskakov's article is in hand and will be forwarded as soon as processing is completed. 1.3(a)(4)

[redacted] 1.3(a)(4)

The Nature of Modern Warfare

by Colonel-General A. Babadzhanyan

With great interest and attention, we read the article of Major-General Goryainov depicting the technical-mathematical bases of future warfare, the article of Colonel-General Gastilovich which, on this technical basis, analyzes the new possible methods for conducting war, the articles of Generals Tolkonyuk and Baskakov echoing in many respects the article of General Gastilovich, and finally, the article by General of the Army Kurochkin which expresses serious criticism of the basic positions taken in the articles of Comrades Gastilovich, Tolkonyuk, and Baskakov.

We must admit that upon first reading the articles by Generals Gastilovich and Goryainov, some degree of doubt was created regarding the proper course along which our military science is developing and, consequently, regarding the correctness of the principles on which our armed forces are being built. However, subsequent deliberations and study of the problem have, in our opinion, shown that in many respects the authors mentioned are wrong: They have simply "laid it on thick", so to speak. True, it must be admitted that such "exaggeration"is useful. It will force our military specialists to analyze the nature of modern warfare more profoundly and to draw practical conclusions on a sound basis with consideration for the new conditions in military theory, as well as in the field of its practical implementation.

The article by General of the Army Kurochkin appears to us to be much more realistic and to reveal in greater depth the possible conditions and nuances of future warfare.

One of the basic problems discussed is the following: Does Soviet military doctrine require fundamental review, is Soviet military art undergoing a crisis? General Gastilovich insists that this is so, while General Kurochkin answers in the negative. This matter is complicated and fundamental.

We must agree with General Kurochkin that we have a military doctrine which dwells on the mass use of nuclear weapons, including those in the megaton class. This is attested to by the report of N.S. Khrushchev to the January 1960 session of the Supreme Soviet, in which he depicted the possible nature of the beginning and

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

the development of modern warfare. However, the principles for the use of the types of armed forces and arms of troops within the framework created by this doctrine are not yet sufficiently elaborated. The views of the authors of both articles coincide on this. They claim that Soviet military-scientific thought, led by the new military doctrine, has only begun to develop and to determine those laws and principles which must be established as the basis for armed conflict in its modern phase.

This is true for both the strategic and operational scales. It is sufficient to imagine, for example, a front offensive operation in which the front troop commander has at his disposal two or three megaton warheads. Or, on the other hand, that there are such weapons at the disposal of the commander of the enemy group opposing the front. It can be stated with complete assurance that the front operation under such conditions will assume forms other than those under conditions when only kiloton warheads are available.

General Gastilovich's important and possibly basic mistake is due to the fact that in defining future warfare, he approached it too narrowly, without taking into account political and economic factors, and without consideration for the existence of various theaters of military operations, each with different conditions.

Proceeding from the premise that there would be a world war with unrestricted use of nuclear weapons, the author arrived at the wrong conclusions regarding the number of armed forces necessary to conduct a war and the nature of the actions of ground troops in offensive and defensive operations of modern warfare.

With a view to analyzing some of the positions expressed in the articles of Generals Gastilovich, Tolkonyuk, and Baskakov, let us dwell in more detail on individual questions of military art.

First of all, it must be recognized that the yield of a thermonuclear weapon is extraordinarily high. It is still difficult for one to grasp and evaluate it. The radiological factor of destruction is particularly great. For example, a 10 megaton bomb is capable of destroying industrial and municipal structures over an area of 1,300 square kms; this is sufficient to destroy any capital. Radioactive contamination resulting from such a burst will be such that under average wind velocity (35 kms/hr) all persons in an area of about 5,000 square kms (a zone 170 x 30 kms) will perish from radiation sickness, and in an area of about 10,000 square kms (a zone 250 x 40 kms)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

about 50 percent of the persons will perish and the rest will lose combat (working) effectiveness for several months, and finally, all those in an area up to 100,000 square kms (a zone 2,500 x 400 kms) [sic] will partially lose combat (working) effectiveness. This means, for example, that an industrial area such as the Ruhr can be knocked out of action for a long time by two-three 10-20 megaton bombs as a result of the destruction of basic installations and of the annihilation of the labor force.

According to the estimates of American specialists, the use of 50 nuclear weapons against the principal cities of the USA would kill off about one half of the total population and would destroy up to 60 percent of all industrial enterprises. According to this same estimate, the USA has a total of 170 urban areas in which the principal body of the population and industrial plants is concentrated. Consequently, the use of 100-120 nuclear weapons over the territory of the USA would knock out up to three fourths of the industry and a significant portion of the population of the USA. Considering the high degree of industrial cooperation in producing complicated military equipment, one can say that such a blow would halt production of armament and supplies for the army and its demise would be only a matter of time.

But what would be the consequences of a similar blow against our country?

The large territorial expanses, the great dispersion of population and industry, and the observance of proper camouflage and secrecy measures will permit a significant reduction in the effect of a similar massive thermonuclear attack against our installations. However, this would only reduce the effect! Results of a strike would be significant enough to require the most extreme human efforts to restore order in the country and to ensure the capability of our armed forces to deliver a counterblow and to seize the strategic initiative.

Under modern conditions, aggressive circles possibly may not risk a war, if only because they recognize the impossibility of depriving the Soviet Union, as a result of one strike, of the capability of delivering a devastating counterblow.

But this situation cannot be permanent. The power of the first surprise attack in modern times is not determined by the supply of warheads but on the availability of the means to deliver them to targets.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

According to estimates, the USA at present has thermonuclear materials in sufficient quantity to build about 2,000 megaton warheads. The NATO countries' basic means for delivery of nuclear weapons on a strategic scale is still aircraft. Our possession of highly effective antiaircraft missile weapons does not allow them the necessary degree of confidence in their capability to deliver nuclear weapons by this means. The strategic missiles at their disposal clearly cannot satisfy the requirements of a major war, and, in addition, their quality is not high, since, according to assertions of the Americans themselves, only 50 percent of the missiles launched reach their target.

This is the situation today. What will the situation be at a future time, when governments which do not now have sufficient numbers of missiles will overcome their shortcomings in this type of armament? In the future, the probable enemy will have a greater capability to deliver surprise massive nuclear strikes in order to destroy a significant portion of industrial targets, administrative-political centers, missile-launching sites, strategic aviation airfields, and other vital areas and installations. Such a powerful, practically simultaneous initial strike can destroy the most important and crucial installations of the country, disorganize national control, disrupt mobilization and deployment of armed forces, and severely reduce the combat effectiveness of the army and the country as a whole.

This is so serious in its possible political and economic consequences that every measure must be taken so that if the imperialists try to start a war it will not begin by a sudden massed enemy nuclear strike.

The peace-loving foreign policy of our Party and the Soviet Government is known to all. It stems from the very nature of a socialist state. We do not want war and our Party is conducting constant work in the direction of preventing a new world war, which would demand huge numbers of victims and would destroy all that has been created by human hands. However, if it becomes evident that aggressive forces have decided on war, and that the initiation of military operations is only a question of a short time, and if we fail to prevent the aggressor's attack by diplomatic means, then it is necessary to wreck the enemy strike by all our available forces and means. Under such conditions, the strategic concept of the armed forces of our country must be based on the total annihilation of all enemy capabilities to accomplish his aggressive schemes during

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

the first days of the war.

The question may be asked: When will these new conditions come about? From what year or what date must our armed forces be guided by the new concept? The number of missiles and launching sites grows gradually, and occasionally in spurts. The precise determination of the period of the transition of the quantity of these means to the new category is difficult and unnecessary. What should be done now and quickly is to prepare and organize our intelligence and the armed forces in such a way that they will be in a constant state of readiness to deliver such a blow against the aggressor.

The possession of missiles, particularly intercontinental, as a means for delivering nuclear weapons, permits the conduct of preparations for an attack in utmost secrecy. Under these conditions, the work of our intelligence organs will be very difficult. Possibly, information about aggressor preparations for an attack will be received only at the last minute before the beginning of an attack. This requires a new approach to the preparation and definition of the stage of readiness of our own means of attack.

Regarding the matter of the numerical size of armed forces, and specifically of the ground troops. We agree with the assertion of General Gastilovich that, in order to accomplish specific strategic and operational tasks in modern warfare, smaller numbers of forces will be required than in past wars. However, in making this conclusion, we must not forget that the number of strategic and operational tasks to be fulfilled in modern warfare will be incomparably greater than in the past.

In the event of a global war, today our armed forces will be required to operate simultaneously in many theaters of military operations, including the Arctic. Considering the wide use of means of mass destruction, which will create heavy demands for replacements in the active armies, and in a number of cases for their full reconstitution, one can say that in modern war more massive armed forces will be needed than those discussed by Comrade Gastilovich.

General Gastilovich considers that the role of ground troops in modern warfare will be essentially that of "occupation". In order to seize countries subjected to massed strikes by megaton bombs, ground troops need only overcome zones of partial and total destruction. Thus, the author excludes the bringing up of large operational and, what is more, of strategic reserves. On the basis of this, one reaches

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

the conclusion that in the Western TVD (Theater of Military Operations) 30-40 divisions would be required to accomplish the war's tasks. There is no need to engage in polemics regarding the number of divisions (30-40 or 50-60). One thing is clear, that a sufficient number of troops must be available to make possible the rapid replacement of large units knocked out of action by nuclear weapon strikes. There will be numerous such situations. It seems to us that General Gastilovich's estimates are too optimistic.

Nor can we agree with the view of Generals Gastilovich and Baskakov that, under modern conditions, the distinction between defensive and offensive operations has been erased. We agree with the authors that the conduct of offensive or defensive operations will be conditioned by the number of nuclear weapons and their delivery means which are allotted to a given front. Let us add to this the fact that the conduct of one or another type of operation will depend essentially on the relative quantities of nuclear weapons and their delivery means available to the front and to the enemy grouping opposing the front.

At the same time it is impossible to agree that an offensive which differs from a defensive one in the purpose of the action will resemble it in the methods of tactical actions of large units (Gastilovich) or with the concept that the difference in conducting offense and defense will be retained only in tactics (Baskakov).

We fully agree with the view of General Kurochkin, who says that mass employment of nuclear weapons does not erase the boundaries between offensive operations and defensive operations, but gives them a unique character requiring the development of new methods for conducting offensive and defensive operations. Actually, what can there be in common between an operation whose goal is to crush enemy resistance and to penetrate into the depth of his territory, and an operation whose goal is to prevent enemy penetration and consequently to hold specific terrain and establish conditions favorable for a switch to a counter-offensive? In our view, such an assertion could have been made only in view of the denial by General Gastilovich that a stable defense is necessary.

Stability is a basic quality of defense, operational included. Without this quality, defense as such ceases to exist and becomes meaningless. Let us imagine, for a moment, the defense of an important economic or strategic area which does not have stability and in which stability is not required. Most probably, such a defense will not

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

accomplish its defensive tasks and the installations defended can be surrendered to the enemy without any particular feeling of responsibility.

Defensive operations must, unquestionably, be stable. However, mass use of nuclear weapons has its impact on this concept. If the previous concept of "stability" included a specific, if one may use the expression, "linearity" (the holding of a specific line) now, under present conditions, stability must be referred to as being established within the depth of a sector of the territory.

Let us clarify this thought. To hold specific zones, positions, or centers, when the attacking enemy has a sufficient number of nuclear weapons, is practically impossible. Therefore, one cannot speak of "linear" stability. The offensive can be halted only by a system of massed nuclear strikes, counterattacks, and counterstrikes. This can be done, however, only within a specific depth of the defense. In each case the rear boundary of the defensive depth must be determined on the basis of specific conditions of the situation, in which the main factor is the relative strength in weapons of mass destruction possessed by the attacker and the defender.

Under these conditions, should defensive zones be established? General Gastilovich says that they should not. We do not agree with this. We know that the enemy will use gaps and open flanks during his attack. Therefore, we can channel the enemy offense along directions which are advantageous to us by establishing zones and centers in specific areas. In addition, defensive structures serve as troop protection against nuclear weapons. It is more advantageous to build defensive structures which serve a dual purpose (the protection of personnel and equipment and increasing the stability of the defense) rather than shelters at concentration areas with the sole function of protection.

We also consider General Gastilovich's view regarding the use of nuclear weapons in defensive operations to be incorrect. He rejects both the necessity for delivering massed nuclear strikes to disrupt the enemy offensive and the desirability of conducting counterpreparations.

The wide use of nuclear weapons changes the method for conducting defensive operations. Now, it is of paramount importance that action be taken to disrupt or to diminish the strength of enemy preparations for the offensive. Massed employment of even a limited number of nuclear weapons can place the enemy in a situation where he may be

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

forced to cancel his offensive. In this case, the greatest significance will unquestionably be attached to counterpreparations directed primarily against the enemy's deployed nuclear means of attack and his troop groupings.

In light of this, the proposal to limit ourselves to day by day and immediate destruction of detected enemy nuclear attack weapons and to individual (to the degree possible) nuclear strikes at varying times against his most dangerous enemy tank divisions which have broken through, sounds strange, to say the least. Even more strange is the fear that a massed strike by nuclear weapons can lead to the growth of a defense into an offensive. First of all, such a growth is unlikely, considering the relative relationship of nuclear weapons, and secondly, it should be welcomed rather than feared.

In conclusion, we would like to dwell on the role of tanks under modern conditions. The development of tanks as an effective striking force from the time of the first world war until now was conditioned by the fact that the tank emerged victorious in the competition with antitank weapons. Today the development and serial production of antitank missile launchers which have a high effectiveness both with respect to accuracy and destructive action, have created a new situation.

In single combat, a tank against an antitank missile launcher, the tank will usually lose. This means that with a high enough concentration of antitank missile launchers on the field of combat, any tank attack can be disrupted and a large portion of the tanks and their crews participating in the attack will be destroyed. But if we consider further that the production of an antitank missile launcher costs several tens of thousands of rubles and that a tank costs several hundreds of thousandsof rubles, then it becomes clear that the use of tanks in their modern concept in warfare is unprofitable both militarily and economically.

In our view, heavy tanks must depart from the scene. They should be replaced by medium and, particularly, light, combat vehicles armed with an automatic multi-round missile launcher having a grazing range of 3-5 kms, equipped with anti-small arms fire, and splinter-proof armor, and capable of crossing water barriers.

The basis for this combat vehicle can be the amphibious tank, PT-76. It must be kept in mind that, under modern conditions, troops must cover great distances on their own power both during preparation

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

for, as well as during the course of combat and that possibly it would be more advantageous to create a combat vehicle with an especially high cross-country capability wheel drive with three or four axles.

The proposed combat vehicles, retaining the basic positive quality of tanks --- stability against the destructive factors of a nuclear burst - would cost much less, would be easier to produce, and would be more effective in their firing action.

* * * *

Not considering that the views expressed in this article are the only correct ones, we trust that a review of the large and basic questions raised by this issue of the Collection will serve to develop individual views corresponding to the modern conditions of conducting an operation.

The Strike Groupings of a Front

by

Major-General of Tank Troops A. Shevchenko

In a modern offensive operation by a front, despite the decisive role played by nuclear/missile weapons, the need to create strong and mobile strike groupings (udarnaya gruppirovka) remains. By the strike grouping of a front one should understand a unit of forces and weapons intended for the destruction of a particular grouping of the enemy by the use of means of destruction and by maneuver. In practice, strike groupings will be comprised of formations included in the composition of a front with their allotted forces and weapons. Since these groupings are intended for the successive performance of tasks in particular directions and to a specific depth, we consider it inadvisable to include in their composition the forces and weapons remaining at the disposal of the commander of the front. A front's forces and weapons may be used in support of the combat operations of several strike groupings and also for the performance of other tasks for the front.

Exploiting the results of nuclear/missile strikes delivered by the weapons of the front and of the General Headquarters (Stavka) of the Supreme High Command (VGK) the strike groupings of a front must be capable of destroying the enemy in short periods and of occupying his major installations and lines in depth.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

During the course of the past war and also in exercises and maneuvers in the postwar period there was and there still is a tendency to create strike groupings chiefly from the large units which combine strike force and mobility, i.e., from tank divisions. In the creation of front strike groupings at the present time, special preference is given to tank armies. It is considered that they constitute "the basis of the strike groupings of the first echelon of a front".[1]

The use of tank armies as the strike groupings of a front under modern conditions will become more difficult. It is known that during a series of recent training exercises there were certain shortcomings in the use of tank armies. The Minister of Defense and the Commander-in-Chief of Ground Troops noted substantial shortcomings in the use of tank armies by both sides at the exercise conducted by the Commander-in-Chief of Ground Troops in 1959. One of the reasons for these shortcomings is the change in the conditions of conducting combat operations brought about by the appearance of new means of combat.

Considerable influence is exerted on the use of tank armies by the state of modern means of intelligence and destruction and also by the enemy's ability to counter the maneuver of a tank army by maneuvering of his own motorized large units. The enemy will concentrate the main efforts of his intelligence on the detection of the tank army and, having detected it, will use a large part of his weapons of mass destruction for strikes against it; this may put the army in an extremely difficult position, sharply reduce its combat effectiveness even before the beginning of combat operations, and also diminish the speed of its advance. As we know, such difficult conditions for operations by tank armies did not exist during World War II.

---

1. Tank Troops and Their Use in Modern Operations. Voyenizdat, 1960, page 31

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

In connection with the fact that it has now become easier to detect the appearance of a tank army in a front and that modern means of combat make it possible to inflict serious damage on it in a short time, the commitment or a tank army to battle will be extremely difficult. Thus, in the September 1959 exercise, the forward movement of the 17th TA (Tank Army) of the "Easterners" was detected by the intelligence of the "Westerners", and during its approach to the line of deployment, surface nuclear strikes with a total yield of about 600 kt were delivered against it. Undoubtedly, under real conditions such strikes would sharply reduce the combat effectiveness of a tank army.

In the past war, the organizational structure of the enemy's infantry divisions (his basic large units) hampered their use for maneuvers intended to contain the operations of tank armies and tank and mechanized corps. Modern infantry divisions are capable of performing these tasks more successfully. Moreover, armored divisions, the number of which has increased, may be used for these purposes.

Modern offensive operations are characterized by more frequent shifts in the efforts of the front's troops from given directions to others. Such shifts demand the rapid creation, in selected directions, of strike groupings composed of a sufficient number of tank large units. If a tank army is used as a strike grouping of a front, its maneuver, in a shift of the front's effort to a new direction, will be impeded. Such a maneuver will be difficult to hide and its conduct will require a great deal of time. In a number of cases, the tendency to use a tank army to perform the most important tasks will result in a situation in which the large units included in its composition will be held in reserve unnecessarily. This was the case during the September 1959 exercises with the 18th Tank Army (TA) which did not take part in combat operations for seven days.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In the course of an offensive operation, tank armies are often obliged to perform tasks which are difficult to fulfil with the forces of tank divisions. In these same exercises, the 16th TA was obliged, by the course of events, to conduct combat operations connected with forcing a crossing of the Dnepr and expanding the bridgehead. The operations of the army were contained, it suffered large losses, and did not succeed in its task. The 17th TA, which was supposed to force crossings of the Dnepr and Pripyat and to operate in wooded terrain, was put in a difficult situation. In the course of the front command-staff exercise held in the Transcarpathian Military District in June 1960, the 7th TA had to resort to combat in order to cross the Carpathians.

In connection with the changes which have taken place in the organizational structure of the troops, it has become more difficult for a tank army to be separated from a combined-arms army. Today, the organization of a combined-arms large unit has changed radically. Rifle divisions have given place to motorized-rifle divisions which are superior in their technical equipment to the former motorized corps which were used as independent mobile groups or within the composition of tank armies. If one takes into account that a combined-arms army may also have tank divisions, it becomes clear that the tank army does not possess the advantage over the combined-arms army that it had in the years of World War II. The modern combined-arms army, even with a small complement (three motorized-rifle and two tank divisions), has approximately the same number of tanks and assault guns (SAU) as a tank army (three tank and one heavy tank divisions).

The difficulty of separating the tank army from the combined-arms army may lead to operations by two armies in a single zone or along a single line, which will adversely affect the performance of combat tasks. The operations of the 2nd TA and the 61st Army

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

(A) in the Pomeranian Operation and also of the 12th Tank Corps (TK) of the 2nd TA and the 5th A in the Berlin operation serve as good examples of this. With a similar accumulation of troops in modern conditions, there may be great losses from enemy nuclear strikes.

It should be pointed out that in using a tank army as a front strike grouping, its safeguarding is made difficult, particularly in the coverage of its flanks and in the consolidation of captured lines. In the September 1959 exercises the fact that the 16th TA was not able to secure its flanks with its own forces was one of the reasons for its encirclement south of Kiev. To safeguard the operations of tank armies, front commanders allotted motorized-rifle divisions to them in a number of exercises.

The use of the tank army as the basic front strike grouping leads in many cases to patterns in the plan of operations and makes it easier for the enemy to find the axes in which the primary efforts of the attacking troops are concentrated.

The difficulties examined above, concerned with the use of tank armies in offensive operations, force one to ask the question: Under modern conditions, does one need tank formations (obyedineniye) at all?

It should be noted that the opinion has been expressed in our military press that in many cases it is advisable to have a tank army of a different composition. Thus, Marshal of Armored Troops P.A. Rotmistrov writes, "The operations of a tank army organized along modern lines and reinforced by two or three divisions were tested in a war game conducted between academies. In this game, its director repeatedly reinforced the tank army with several divisions in order to make it possible for it to break away faster from the main forces of the front and to develop a swift offensive into the depth of the enemy's territory".[1] In this case, a formation superior

---

1. Collection of Articles of the Journal "Military Thought", No. 6 (50), 1959, page 18

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

in offensive capabilities to the tank army of the usual composition was created. Actually, this was just a combined-arms army composed chiefly of tank divisions.

In our view, under modern conditions, it is inadvisable to have such formations as the tank army. Front strike groupings should be combined-arms armies which include the necessary number of tank divisions concentrated on the most important axes. The role of a front strike grouping may be successfully performed by a combined-arms army comprised of two or three tank and two or three motorized-rifle divisions.

A modern offensive may be conducted under the most varied conditions. Durings its course, in certain directions and at certain times, a task which has been assigned may be performed more successfully by a large unit possessing the qualities of a tank division and, in another direction and at another time, by a large unit with the qualities of a motorized-rifle division. In view of this, tank and motorized-rifle large units should be combined in a formation which comprises a strike grouping.

Certain comrades who persist in believing that it is necessary to retain tank armies and their special role in a future war are, at the same time, forced to admit that "The modern flexible organization of combined-arms armies which allows the motorized-rifle and tank divisions included in them to vary in their composition and which permits their transfer in case of necessity from one army to another, in order to create an army of the required make-up, favors, to a large degree, the effective use of the army in an operation. The new organization of a combined-arms army permits the modern front to be more flexible in its use of tank divisions in the decisive directions of an offensive and of armored troops in an offensive operation as a whole".[1] And, further, "The flexible

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

organization of our new combined-arms army, which will include a strong armored grouping within its composition, permits a front to perform the tasks assigned to it without a tank army".[2]

Also worthy of attention in this respect is the statement of Marshal of Armored Troops P.A. Rotmistrov that "In some instances it will seem more expedient to reinforce the composition of a front, not with tank armies, but with individual tank large units which, together with the regrouping of the large units in the armies of a front, can be set up as a combined-arms army (or armies) of the required composition which approximates to a tank army in structure".[3]

The experience of postwar exercises shows that the need to make up for the inadequacies of a tank or combined-arms army sometimes makes it necessary to attach motorized-rifle divisions to a tank army or to increase the number of tank divisions in a combined-arms army. In such situations, tank and combined-arms armies will be distinguished from one another chiefly by the ratio of tank to motorized-rifle divisions. This ratio must be in accordance with the particular situation: In certain cases, the number of tank divisions in a formation must exceed the number of motorized-rifle divisions, in other cases, there must be fewer of them. One thing which is indisputable, however, is that tank divisions today must be used not in a homogeneous formation (a tank army), but in combination with motorized-rifle divisions, i.e., within combined-arms armies. In the course of a front offensive operation, depending on the situation (the nature of the enemy's operations, the conditions of the terrain, etc.), the ratio between tank and motorized-rifle divisions in armies may change sharply in one direction or the other.

2. Ibid. Page 68

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

A combined-arms army, which consists mainly of tank divisions, can fulfil the role of a front strike grouping with great success. However, a combined-arms army consisting of eight or more divisions will become cumbersome and of poor mobility. In this case, a strike grouping may in practice be composed of several tank and motorized-rifle divisions (three or four). More precisely, this will be, as it were, the skeleton of the strike grouping; essentially, the divisions comprising it will perform the tasks which are now assigned to a tank army.

A combined-arms army, which has a sufficient number of tank divisions, will possess great striking power and firepower, maneuverability, and the ability to advance at a high rate. The availability of such armies would produce favorable conditions for the concealed establishment of strike groupings and for the delivery of surprise strikes against the enemy.

The reinforcement of combined-arms armies with tank divisions by the successive introduction of the latter from the reserves of the front ensures the necessary dispersal of forces and weapons; divisions will not be concentrated in limited areas, as sometimes happens when a tank army is committed to battle.

More favorable conditions are created for changes in the direction of the main strike. By introducing individual tank divisions, supplementing those of the combined-arms army already operating in the zone, a strong grouping can be created in the required direction in a shorter time and in a concealed fashion. At the same time and to the extent necessary, a reserve of tank large units may be created in a front by detaching them from armies in which there is no longer any need to center the basic efforts of the front; divisions from this reserve may subsequently be put into the zones of other armies. Such use of tank divisions prevents their being held in reserve for a long time and is conducive to the wider maneuver of large units on a frontal scale.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In the type of organization of strike groupings which we propose, one can perform more successfully the task of replacing tank divisions with motorized-rifle divisions during the course of combat operations, one can avoid operations by two formations in one zone, ensure better coordination between a tank grouping and other large units of an army, and can also create favorable conditions for the consolidation of captured lines and for the protection of the flanks of the strike grouping.

As is known, a tank army contains a heavy tank division. We consider that such a large unit must serve as an instrument (sredstvo) of the front. Although, essentially, a heavy tank division can perform all the tasks which are carried out by a tank division, it is most advisable to use it for battle with the enemy's tanks. The nature of modern combat operations demands the widest maneuver by a heavy tank division in the zone of a front, but this maneuver is limited by its organizational link with the tank army. Both during the combat operations of a tank army and before its commitment to battle, this powerful antitank instrument is frequently held in reserve. The heavy tank division which forms the reserve of the front will be used first and foremost as an effective antitank instrument. Naturally, in case of necessity, it may be transferred to the composition of one or another of the combined-arms armies.

The foregoing leads to the following conclusions. In view of the emergence of new means of combat, of improvement in the means of intelligence, and because of the change in methods of combat operations and in the organizational structure of troops, the need for the fulfilment by tank armies of "specific" tasks in developing the success of an offensive has passed; the use of tank armies as strike groupings of a front has become more difficult. The role of the strike groupings of a front may be performed more successfully by combined-arms armies, whose composition must correspond to the particular conditions in which the operation is being carried out.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The shift to a new troop structure which rejects tank armies, which we propose, does not entail great difficulties. The implementation of such a measure is extremely necessary and will permit generals and officers to acquire skill more quickly in a new solution to the tasks of setting up a front's strike groupings.

On the question of the advisability of creating front strike groupings by the wide maneuver of tank divisions and by their use in combination with motorized-rifle divisions -- we consider this to be the best solution to this problem, given the present-day organization of troops (with tank and motorized-rifle divisions). At the same time, we consider it necessary to work on the creation of unitary (unitarnaya) divisions which are capable of the successful performance of the highly diverse tasks which arise in the conduct of modern combat operations.

DATE OF INFO: 1960

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "Some Conclusions on the NATO Armed Forces' Exercise SIDE STEP", by Colonel-General S. Ivanov.

This article appeared in the 1960 Second Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. It is distributed only within the Ministry of Defense down to the level of Army Commander.

Headquarters Comment: Some of the detail on the attached map is unclear; although the majority of the designations can be accepted with confidence, there is some room for error in the breakdown of the various army corps and similar small print. It is also difficult to distinguish between the lines of the successive positions. The transliterated letters "N/N" indicate military units without designations.

Some Conclusions on the NATO

Armed Forces' Exercise

"SIDE STEP"

by

Colonel-General S. Ivanov

The leaders of the aggressive NATO Bloc plan to launch a future World war primarily by means of a surprise attack against the countries of the Socialist Camp. One cannot rule out their launching a world war after a period of sharp political tension or local wars. They envisage carrying out preparations for an aggressive war in such a way that they will be interpreted as purely "defensive" preparations, not only by the enemy but also by the personnel of the armed forces and by the populations of the member-countries of the bloc.

Decisive significance is attached to the initial period of the war, in the course of which it is intended to destroy the atomic potential of the enemy, to disorganize the national administration and economy, to disrupt the mobilization and deployment of the armed forces, to undermine the morale of the people, and in this way to achieve the immediate strategic goals of the war and to predetermine its outcome to their benefit. For the fulfillment of these tasks it is planned to bring to bear the greatest possible number of forces and means capable of using nuclear weapons.

The operational plans for the initial period of the war are periodically tested in operational-strategic exercises, during which different variations for launching and waging war given various degrees of preparedness of the armed forces are studied and tested.

From this point of view, the command-staff exercise, SIDE STEP, conducted in September 1959 with the participation of troops of the Allied Armed Forces of NATO merits special attention. In the importance of the problems which were being worked out, in its sweep and in the composition of the participants it was one of the largest exercises of recent years. It covered almost the entire area of Europe, of the Atlantic, and of the Mediterranean.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The commanders-in-chief and staffs of the armed forces of the North European, Central European, South European, Atlantic and Mediterranean theaters of military operations, the commanders and staffs of the branches (vid) of the armed forces and of the regions (rayon) in the theaters of military operations, the commanders and staffs of army groups, the tactical aviation commands of field and air armies, the commanding officers and staffs of army corps (altogether 19) and divisions (51), and also the commanding officers and staffs of atomic artillery, guided missile and free rocket units participated in the training exercise.

In addition, the central directorates of defense ministries, commands and staffs of military-territorial organs, rear elements (organ tyla), the central directorates of Ministries of Internal Affairs, of Transport, of the Merchant Fleet, of Economics, of Health, of Communications and a number of other agencies from all European member-countries of NATO participated in this exercise.

Exercise SIDE STEP consisted of four exercises which were conducted according to a common plan and against the background of a single strategic situation.

The most important were the exercises of the Allied Armed Forces of NATO of the Central European and of the Southeastern part of the South European Theaters of Military Operations in which problems of preparation and conduct of the first operations in the initial period of the war were worked on. The basic goals set were: perfection of the system for bringing the allied and national armed forces to combat readiness; testing the methods of using nuclear arms in the course of the initial operations; the organization of command; the coordination of forces and means and of the comprehensive support of military operations.

At the same time, a rear area exercise was conducted in all European theaters of military operations with the aim of testing the existing system of supply, as well as of studying the ability of member-countries of the bloc to support their armed forces with supplies independently. American troops stationed in Europe conducted a special rear area exercise, "RAPID SERVICE" ("Bystraya podacha"), in which questions of material-technical support of nuclear ground troops units were studied.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

On the basis of a common operational-strategic situation, a naval exercise was also conducted on defense of communications and on control of merchant shipping, in which the coordination between the Allied NATO staffs and the national staffs and establishments on questions of defense of naval communications and of insuring uninterrupted merchant navigation in the beginning of the war was worked on.

Exercise SIDE STEP was under the command of the Supreme Commanders-in-chief of the Allied Armed Forces of NATO in Europe and on the Atlantic. For direct command of the exercise, directing staffs were created at all staffs of formations and large units of the armed forces, as well as at the commands of military-territorial organs of various establishments participating in the exercise.

This exercise was conducted against a background of "military operations" in Europe and in the Atlantic area between the armed forces of NATO (BLUE) and the armed forces of the Warsaw Pact (ORANGE).

According to the given situation, the war between BLUE and ORANGE began as a result of gradual sharpening of international tension lasting for more than five months. The situation and the actions of the two sides were worked out so as to place all the blame for unleashing the war on the ORANGE , that is, on the Socialist countries, while the imperialist states, the NATO members, would be represented as victims of aggression, supposedly forced to carry out counter measures to the "aggressive" actions of ORANGE. If this rather artless camouflage is discarded, the predatory plans and actions of the bloc headed by the USA can be seen distinctly through the entire idea and course of the exercise.

How then was the development of events up to the outbreak of war envisaged?

The first period (January-March 1959) was characterized by "international equilibrium". This was followed by a period of "international distrust" (April-June), during the course of which relations between the leading countries of the political groupings deteriorated. The reason for this was supposedly a mutually prejudiced appraisal of the actions of the two sides, doubt of the sincerity of each other's policies and also the deadlock

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

which had been reached in the negotiations of the leading powers on control of the production of nuclear arms (just exactly on control, rather than on prohibition of nuclear arms).

The period of distrust was followed by increased international tension (July-August).

Since the international situation "continued to intensify", the NATO command announced a threatening situation on 1 September which continued for two weeks (until 14 September). During this period all bloc participants mapped out measures for partial mobilization, for bringing the armed forces to combat readiness, and for establishing the necessary order in the rear. After this, the system of alerts adopted by NATO was put into effect (14-19 September), and during this time the armed forces were brought to full combat readiness and were deployed in operational formations.

In this manner, events gradually developed up to the beginning of armed conflict. Evidently the NATO command reckons that under these conditions the aggressive bloc will succeed in completely preparing for war against the countries of the Socialist Camp, and at the same time in disorienting world opinion, with which, it is true, the imperialists do not now especially concern themselves. However, this by no means signifies that they plan only this method of preparation for unleashing war. If we analyze other exercises, especially the practical measures of NATO in preparation for future war, then it is not difficult to be convinced of the fact that they place first priority on a surprise attack against the countries of the Socialist Camp, secretly prepared in a very short time.

Further events developed in the following manner: ORANGE, having concentrated three fronts (75 divisions) in the Central European Theater of Military Operations, and also considerable forces (24 divisions) on the Balkan Peninsula and in the Caucasus, launched massed air and missile nuclear strikes at 0530 hours on 19 September against airfields, the means of nuclear attack (sredstvo yadernogy napadeniya), ports, large communication nets, and against BLUE troops; simultaneously, they took the offensive with groupings of ground troops. In the Central European theater, ORANGE directed the main attacks in the directions of: Magdeburg; Hanover; Muenster; Eisenach; Frankfurt am Main; Kaiserslautern. Auxiliary attacks were launched in a series of directions (diagram I).

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

On the Balkan Peninsula, the main attack was directed against Istanbul and two attacks against Salonika from the territory of Bulgaria and Albania. From the Caucasus, the offensive was carried out in a series of directions deep into Turkish territory.

BLUE carries out a nuclear offensive /attack/ using strategic, tactical, and carrier aviation, missiles and other ground troop weapons. The groupings of ground troops on all fronts conduct defensive actions and by 24 September fall back to a depth of from 50 to 150 km, where they stop the offensive of ORANGE. At the same time BLUE concentrate their reserves and prepare to go over to the counter attack. At 1500 hours on 25 September the exercise was concluded.

Let us briefly examine the grouping of ground troops set up at exercise SIDE STEP at the beginning of military operations.

In the Central European Theater were deployed the two army groups - the Northern and the Central - which existed there in peacetime. The Northern Army Group consisting of 10 divisions, one brigade group, and two regiments, strengthened by four atomic support battalions (divizion atomnoy podderzhki), and a "Corporal" missile regiment was deployed in a 280 km strip (polosa) along the Weser and Fulda Rivers, 100-120 km to the west of the border between the FRG and the German Democratic Republic.

The Central Army Group consisting of the 7th American and the 1st French Armies (14 divisions, one tank group, four separate regiments (otdelnyy polk) and 24 atomic support battalions) deployed in a 475 km strip along a line located 30-50 km from the GDR border and in places up to 120 km.

The desire of the NATO command to cover the entire strategic front with divisions to an average operational density of 30 km per division attracts attention. In front of the defense line a cover zone (zona prikrytiya) is organized, where reconnaissance units operate and possibly, individual units from the first echelon divisions. Cover units are distributed along a considerable front. Their mission is to carry out holding actions in front of the basic defense line. They are incapable of offering serious resistance to the advance of our troops.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In the strategic reserve of the NATO command there were about 10-12 divisions from the complement of the first echelon of NATO (French and Belgian army corps, a Dutch division, West German units formed by mobilization, as well as large units transferred from North Africa, North America and England).

Approximately the same concept was applied to the operational formation of NATO forces on the Balkan Peninsula and in eastern Turkey.

Thus, in exercise SIDE STEP the NATO command organizes a typical linear defense along the entire strategic front, deploying the basic mass of its divisions in a single line. Such a defense condemned the ground troops to passivity, and consequently led to the instability of the entire defense, which was faced with strong offensive groupings of ORANGE ground troops superior to a significant degree to the NATO forces.

At first glance it may appear incomprehensibile that the NATO command forms a defense in the theaters of military operations, which can not withstand an offensive when nuclear arms are used. If one analyzes the entire course of the exercise, however, then it is not difficult to be convinced of the fact that the NATO command in the exercise relied basically not on the action of ground forces, but on the use of a large quantity of tactical and strategic nuclear weapons, on the conduct of a nuclear offensive. Under these conditions, the ground troops which had been brought to readiness by the beginning of military operations, were entrusted with the task of covering the base locations of nuclear means (prikryt bazirovaniye yadernyye sredstva) and insuring the carrying out of a nuclear offensive and the deployment of the strategic reserves. By means of nuclear attacks, the NATO command evidently counted on inflicting such destruction on the enemy as to insure that its ground forces could go over to the offensive without engaging in----(4 or 5 words missing)----battles.

It is well known that ground troops are assigned an active role in the NATO plans of preparation for future war, especially in the Central European Theater. According to these plans, after a successful nuclear offensive, groupings of NATO ground troops must go over to a decisive offensive with the mission of destroying the troops of the Warsaw Pact countries, of occupying the territories of the GDR, Poland, Hungary, Czechoslovakia, and of carrying

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

military operations onto the territory of the USSR. The most responsible role in the offensive is entrusted to the armored and airborne troops, who must quickly and effectively exploit the results of the nuclear strikes by decisive actions.

If for any reasons the surprise nuclear attack of the Western Bloc does not achieve the expected results, defensive operations by the ground troops are envisaged, in order to win time for the concentration of reserves and the creation of conditions for going over to the counter-offensive. It is calculated that this goal may be achieved in a short period. Defensive operations are also based on the massed use of nuclear weapons, on broad maneuvering of forces and means, on the carrying out of counter-attacks and counter-blows by highly mobile units and large units, and on the wide use of all possible obstacles. Facts at our disposal indicate that the defensive grouping of ground troops set up in the exercise did not fully ensure the conduct of such a defensive operation.

Let us examine the course of combat operations in exercise SIDE STEP.

According to the plan, ORANGE started military operations by striking massed nuclear blows by missile troops and aviation with the simultaneous taking of the offensive by the ground troops. Actually the game was conducted differently. ORANGE launched the first massed nuclear strike at 0530 hours on 19 September (on the Balkan Peninsula at 0500 hours), but the commanders of the exercise gave the signal for the use of nuclear weapons by BLUES at 0340 hours on 19 September, that is, almost two hours before the "enemy" attack. It follows that the first nuclear blow at the exercise was struck by the NATO troops, which is what they are indeed preparing for. This was a pre-emptive (uprezhdayushchiy) and not a "counter" (otvetnyy) nuclear attack, as the NATO command was trying to show.

From the first minutes of the war the NATO troops conduct a nuclear offensive on a broad scale. The nuclear offensive planned by our probable enemies in the initial period of the war can be arbitrarily divided into two parts. The first and main part is the destruction of objectives in the Soviet Union throughout the entire depth of its territory by strategic nuclear means of attack. This part of the nuclear offensive was not played out in the exercise, but it was taken into account. The second part of the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

nuclear offensive involves the destruction of objectives on the borders of the theaters of military operations and partly on the territory of the USSR and of the other Socialist countries up to a depth of 1,000 km from the front line by forces and means under the jurisdiction of theater commands.

The principal means of nuclear attack in the theaters of military operations are tactical aviation and cruise missiles (samolety-snaryady) of the "Matador" type, which are at disposal of the command in the theater. The missile weapons and atomic artillery of the ground troops which are under the direction of the commands of army groups, field armies, and army corps, and in the US Army - of divisions as well, are also used.

The following missions were entrusted to tactical aviation in the course of the nuclear offensive; the destruction of the means of nuclear attack (sredstvo yadernogo napadeniya); the neutralization of radiotechnical equipment; the disruption of communications; the destruction of reserves and of other enemy objectives; the support of their own troop operations.

The battle against the means of nuclear attack was considered by the NATO command as one of the most important tasks of the nuclear offensive. This was conducted by the destruction of airfields and missile launch sites, nuclear weapons, aviation and missiles, and of command centers. The final goal of this battle was set as the achievement of nuclear superiority over the enemy.

To disrupt communications, bridges and road junctions were destroyed, and barriers were created by atomic means. This was also intended to disrupt and interdict the transport of troops and supplies, to make difficult the maneuvering of troops, and to prevent the bringing up of strategic reserves.

Tactical aviation was used for the direct support of ground troops by striking blows against the combat formations of enemy troops, enemy reserves, command posts, depots, and also by conducting aerial reconnaissance. However, only a limited number of aircraft was made available for the direct support of ground troops.

The organization of the centralized control (upravleniye) of nuclear strikes in the South European Theater of Military Operations attracts attention. The resources of the 6th Fleet and the air

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

command were combined. For this, an operational center for joint operations was formed at the 6th Allied Tactical Air Command; in this center there were representatives of the Supreme Commander-in-Chief of NATO Armed Forces in Europe, of the commander-in-chief of the armed forces of the theater and of the commanders of the ground forces, the air force, and the navy. This center received requests from field and air armies for nuclear strikes, took decisions and issued the necessary instructions. Under this system, more than two hours elapsed from the moment intelligence information was received concerning identified targets for nuclear strikes to the time an order was issued for their destruction.

Operational-tactical missiles and atomic artillery were used to strike nuclear blows against objectives in operational-tactical depth and to support the combat operations of the ground troops. The majority of the missile and atomic artillery units was alloted to the army corps. A "Corporal" missile regiment was left under the command of the Commander of the Northern Army Group, while two "Redstone" missile groups (grupa) were under the command of the Commander of the 7th American Army.

Available information, though incomplete, concerning the use of nuclear weapons in exercise SIDE STEP attests to the significant increase in the number of nuclear strikes during the first days of the operation in comparison with previous exercises. Thus, the 4th Allied Tactical Air Command used 180 nuclear units (yedinits) during the first 38 hours of the war, the 7th American Army used about 205 nuclear rounds (boyevyye pripasy) in six days. In the South European Theater of Military Operations 313 nuclear rounds were used in the six days of war, 255 of which were used during the course of the first three days.

The experience gained in working on the problems of the use of nuclear weapons in exercise SIDE STEP confirms the existence of plans by the NATO command for the use of sudden massed (several - words missing) - with the aim of winning nuclear superiority, inflicting defeat on enemy troops, changing the strategic situation to their advantage, and insuring that their ground troops can go over to the offensive. The implementation of these plans in a future war can cause great damage to our armed forces in the theaters of military operations, unless timely effective methods to disrupt the nuclear offensive of the enemy are undertaken by our side at the very beginning of the war. In this connection,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

it is worth noting several weak points in the so-called nuclear might of NATO. The basic means for using nuclear weapons in the theaters of military operations by the probable enemy remains tactical aviation, against which combat is not a complex problem at the present time. A large proportion of the nuclear weapons of the NATO ground troops consists of the cumbersome 280 mm cannons and 203.2 mm howitzers, the annihilation of which does not present any special difficulty either.

In the exercise, a great deal of attention was given to the defeat in combat operations of the ground troops (proigrysh boyevykh deystviy sukhoputnykh voysk). Although these questions have not been sufficiently clarified, the following conclusions may still be made on the basis of available information.

Holding actions in the cover zone went on for one day. By the end of the day on 19 September, ORANGE approached the basic line of defense having negotiated a distance of from 30 to 120 km. From 20 to 24 September NATO troops carried out defensive operations and were forced to retreat with continuing resistance in all directions. The general depth of the withdrawal was on the average 100-150 km, the average tempo of the withdrawal was 10-15 km a day in major directions (na glavnykh napravleniyakh), and 20-30 km a day in secondary directions. The withdrawal was accomplished evenly, almost along the entire front, under cover of massed nuclear strikes. In the course of the defensive engagement, no active operations of any kind were apparent on the part of the groupings of ground troops. By the end of 24 September the front had stabilized. It can be supposed that from this line (rubezh) it was planned to go over to the counter-offensive with the concentrated strategic reserves, who had not participated in the defensive engagements.

The indicated method of conducting the defensive operations of NATO troops in exercise SIDE STEP has its strong and its weak sides. The strong side of the defense is the massed use of nuclear weapons, while its weak side may be considered to be the shallow linear formation of the ground troops and their insufficient aggressiveness during the course of the engagement. In order to shatter such a defense, it is necessary to destroy the means of nuclear attack and to organize skillfully the operations of mobile groupings of troops in the most important directions with the aim of quick penetration to a great depth and the conduct of maneuvering operations. As far as the reserves who have concentrated in the

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

rear are concerned, they can also be uncovered and crushed by nuclear strikes. However, in the preparation of our armed forces it is necessary to assume that they will have to conduct offensive operations in the beginning of a future war under more complex conditions and against a more aggressive enemy.

Let us examine in more detail the more important questions which were worked out in exercise SIDE STEP.

First of all let us consider the measures taken by the member-countries of the aggressive NATO Bloc in preparing for and launching the war. The study of these measures was one of the important goals of the exercise. Incidentally, by these measures one may judge to a certain degree the actual plans of the probable enemy in regard to the unleashing of war against the countries of the Socialist Camp.

In the period of mounting international tension, that is approximately two and a half months prior to the beginning of the war, a series of concealed measures are taken in the NATO countries in preparation for war. With the introduction of a threatening situation preparation is intensified. The NATO Command looks upon the threatening period as a period of direct preparation for war. Under various pretexts (conduct of exercises, various call-ups and other "usual" measures), a concealed and comprehensive build-up of the Bloc's preparedness for unleashing an armed conflict takes place during this period. First of all, it was planned to intensify construction and repair work at all installations (obyekt) of major military significance, with a simultaneous discontinuation of work at secondary and non-military installations. Government control was established for the distribution and consumption of fuel and critical raw materials; the security of air-fields, storage depots, pipe lines, staffs, communications centers, and other important installations was strengthened; measures were carried out on a broad scale for antiaircraft defense and anti-atomic protection; the evacuation of the most important enterprises from border areas was planned.

Ten days prior to the beginning of military operations the transfer of French first-line large units and units from North Africa to France and onto the territory of the FRG begins. At the same time secret partial mobilization is carried out in a number of NATO member-countries and the building up to prescribed strength

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

of large units of the first echelon and the reserves; intelligence is activated as well.

In exercise SIDE STEP the introduction of a threatening situation did not signify change over to martial law. Martial law was introduced on 14 September, that is, five days before the war, when the Supreme Commander-in-Chief of the Allied Armed Forces of NATO received authority from the Permanent NATO Council (its highest political body) to put the alert systems into operation.

Two alert systems have been worked out in NATO: the military alert system, and the so-called official alert system. The first is brought into operation by the Supreme Commander-in-Chief of the Allied Armed Forces of the Bloc even without the sanction of the NATO Council in that instance when armed conflict may be suddenly unleashed within a one to 36-hour period. In this system measures of a purely military nature are carried out -- bringing to combat readiness mainly the Allied Armed Forces.

The second alert system is brought into operation by a resolution of the NATO Council in that instance, when the military-political situation is aggravated relatively gradually. This system includes a simple, reinforced and a general alert, and signifies general political, military, and economic preparation by the Bloc for entry into war. It is important to note that the Supreme Commander-in-chief of the Allied Armed Forces of NATO is granted the right to independently declare a simple and reinforced alert in case of extraordinary circumstances.

In this manner, the military command of NATO, which is in the hands of the USA, has in essence unlimited authority to the extent of unleashing war, without considering the opinions of the other Bloc members. The alert declared by the Secretary of Defense of the USA, Gates, on the eve of the meetings of Chiefs of State in Paris, does not enter into the NATO alert system. This alert is considered to be an internal affair of the USA.

Exercise SIDE STEP was played out (3 or 4 words missing) alerts.

A Simple Alert was declared at 1700 hours on 14 September. On the basis of it the law on the state of emergency goes into effect in the member-countries of NATO. Secret mobilization

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

measures are carried out on a broad scale, military reserves are called up, the units and large units assigned to the disposal of the NATO Command are brought up to wartime strength, as are the cadre units of national subordination. Armed forces in areas of permanent disposition are brought to combat readiness, as are the troops of territorial and local antiaircraft defense, the system of shore defense, etc. Reserve units of various branches of the service are formed, and new units of national defense forces (vnutrennaya oborona) and various units of special designation are created. The border defense, and the antiaircraft, anti-atomic, anti-chemical, and anti-bacteriological defense of troops, of the population, and of military and non-military installations are strengthened. The wartime communications system is brought into operation, and preparations are made for anti-communications obstructions (zagrazhdeniye) and destruction. The movement of material, technical and medical supplies into the zone of combat operations is begun. At the same time many other measures are also carried out (the limiting of non-military deliveries, partial evacuation of the means of transport from border areas, preparation for the evacuation of the population from combat zones, establishment of control over refugees, intensification of counter-intelligence, etc.).

Two days before the beginning of military operations a Reinforced Alert is declared. In these two days formations and large units are deployed along lines and in positions in accordance with the operational plan, and aerial reconnaissance is significantly increased. The Border Guard is replaced by ground troops. At this same time, the delivery of nuclear weapons to airfields and to firing positions is organized, and all the reserves of material supplies of the troops are brought up to the established norms. Evacuation of supply depots, enterprises, raw material reserves, and the means of transport from border areas to the rear is organized on a broad scale, censorship is introduced, and the means of electronic warfare (sredstvo radio-voyny) are readied for activation.
The carrying out of the above-mentioned measures upon the declaration of a Reinforced Alert two days before the beginning of military operations has been noted in a number of training exercises. This indicates that the NATO Command is striving to limit to the utmost the time needed for deployment of armed forces and operational formations and their arrival in attack positions prior to the beginning of military operations.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

The order of the Supreme Commander-in-Chief to use nuclear arms was given 26 minutes later, i.e., at 0340 hours.

We have examined in detail the measures carried out by the NATO Command in exercise SIDE STEP in the way of preparations for unleashing war. Of course, these are far from all of the measures which will be carried out in an actual situation. For this reason, our intelligence organs are faced with a complex and responsible mission -- to keep all the preparations of the probable enemy for unleashing a new war under constant observation in order to give timely warning to our armed forces.

Of all the measures carried out by the NATO Command in the way of preparations for unleashing war, mobilization of the armed forces of member-countries of the aggressive bloc merits special attention. In exercise SIDE STEP, secret partial measures for building up the armed forces through mobilization started 20 days before the beginning of military operations.

Five days prior to the beginning of war the scale of secret mobilization in all the member-countries of the aggressive NATO Bloc broadened significantly. We do not have full information concerning the specific form taken by the development of mobilization in this exercise. However, if a number of training exercises and certain other measures of the NATO Command are analyzed, one may come to the following conclusions.

In accordance with existing agreements, 86 divisions and a number of separate brigade groups, units, and subunits were assigned to the Allied Armed Forces from the 109 divisions available in the NATO countries at the beginning of 1960. However, of these, only 50 divisions, and 23 brigade groups and separate units were subordinated to the Allied Command. The remaining large units and units remain under the subordination of national commands as part of the troops of the first and second echelons.

The large units subordinated to the Allied Command are maintained in peacetime at full TO & E strength and do not require additional build-up through mobilization. Almost all of them participated in the exercise and were deployed in operational formations two days prior to the beginning of war. The members of NATO provided the following number of divisions: USA-5, FRG-8, England-3, France-4, Turkey-15, Greece-8 divisions. A small

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

number of divisions were provided by Belgium (two divisions), Holland (two divisions), and Portugal (one).

The first echelon of NATO is comprised of 16 divisions and four brigades. In peacetime, they are maintained at 60 percent personnel strength and 100 percent equipment strength. Five days are alloted for their mobilization build-up. It must be assumed that these divisions could be mobilized and fully ready by the beginning of war, although information is lacking about their use in the exercise.

The remaining 20 divisions which comprise the second echelon of NATO, are kept at only 25-30 percent strength during peacetime. It would require 10-20 days to bring them to combat readiness.

What base do the NATO countries have for the build-up of ground troops through mobilization?

In the USA, in addition to the existing 15 regular divisions (of which 5 divisions are in Europe) there are 52 National Guard and Army Reserve divisions (about 1.5 million men), a significant part of which systematically undergoes combat training. The Inactive Reserve consists of about 500 thousand men. In this manner, the USA has at its disposal a trained reserve of up to 2 million men. In the USA much attention is being given to the problem of insuring rapid mobilization and the reinforcement of troops deployed in overseas theaters of military operations.

The FRG had 11 divisions at the beginning of 1960. When the Simple Alert was declared (14 September), assembly points for mobilization were set up in Western Germany and the call-up of reserves was started under the guise of refresher training. By 17 September it was planned to bring all large units and units of the Bundeswehr to a full wartime complement, to form a considerable number of new units, and to form personnel reserves. Specifically, reserve battalions were formed in each of the eight divisions under the subordination of the NATO Command. In military districts 57 reserve training battalions were formed, which were deployed in areas adjoining the western border of the FRG. The total number of enlisted and non-commissioned officer personnel in the organized reserve by 17 September was 78 thousand men, and about 500 reserve officers. In addition - (several words missing) - men who had passed the examination but who had not served in the Bundeswehr.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In Great Britain at the beginning of 1960 there were six divisions and 13 brigades and brigade groups. The base for the build-up of ground troops in wartime is the territorial army, consisting of 10 divisions which in peacetime are kept at 70-80 percent strength.

In other NATO member-countries contingents of military trained reserves are formed. Large units and units of reserves similar to the American and English ones do not exist in the majority of these countries at the present time.

It would not be correct to evaluate the potential build-up of NATO armed forces through mobilization in terms of divisions of ground troops. Under contemporary conditions the evaluation of the probable enemy's potential for the means of nuclear attack acquires decisive significance. Means of this type which are available to the NATO Command are: tactical aviation, cruise missiles "Matador" and "Mace", tactical missiles ("Redstone", "Corporal", "Honest John", "Lacrosse", "Little John"), and atomic artillery (280 mm cannon and 203.2 mm howitzers). As is known, the strategic means of nuclear attack have not been put at the disposal of the NATO Command, they are in the hands of the Anglo-American command and may be used in addition to the existing forces of NATO.

At the present time, plans are maturing for the creation of allied strategic nuclear forces within the Western European Alliance which includes Great Britain, France, FRG, Italy, Belgium, The Netherlands, and Luxemburg, that is, not all the members of NATO. Evidently, what is intended is to create air force and IRBM units capable of using nuclear weapons. These units are considered to be the basic means of war in Europe. For the present, no such allied strategic nuclear forces as yet exist in Europe. In exercise SIDE STEP, operational-tactical nuclear forces were used.

By 17 September all the tactical aviation forces available to the Allied NATO Command were brought to full combat readiness. In the Central European Theater of Military Operations the 2nd and 4th Allied Tactical Air Commands, composed of 115 squadrons (about 2500 aircraft, including about 1,500 fighters-bombers and more than 500 fighters of the Air Defense), were readied. In addition, the USA and England allocated about 1,000 fighter-bombers and fighters of the Air Defense. This number of aircraft basically conforms to the combat strength of NATO aviation in peacetime.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In the South European Theater of Military Operations the 6th Allied Tactical Air Command was brought to readiness. In addition, two tactical air squadrons were transferred to this theater from the USA and the carrier aviation of the 6th Fleet was used.

Significant forces of tactical aviation remain under the subordination of the national commands of the USA, England, and France. It was also planned to bring this aviation to combat readiness. In line with this the principal members of NATO are creating aviation reserves for replacing losses. The best are the Air Force reserves of the USA (the National Guard and the Air Force Reserve), which can also be brought to combat readiness.

Tactical missiles and atomic artillery are for the present under the command of the USA and, in part, England. At the present time, there are 48 battalions of guided missiles and free rockets of an operational-tactical designation and atomic artillery concentrated in the European theaters, of which 36 battalions are located in the Central European Theater of Military Operations. Evidently all of them took part in the exercise. In the last two days before the beginning of the war it was planned to deploy all these units in the appropriate areas and to equip them with nuclear weapons. The NATO Command considers that there is an insufficient quantity of these means of nuclear attack to support the combat operations of the allied ground troops. For this reason it is planned by 1963 to bring the number of battalions, together with the former ones, to 130 missile battalions of operational-tactical designation.

In this manner, exercise SIDE STEP and a number of other training exercises indicate that the NATO Command evidently plans to carry out in advance secret, comprehensive measures for the build-up of the armed forces through mobilization under conditions when war is preceded by a period of sharp political tension. At the same time it is known, that in recent years in the West many of the military ideologists of imperialism are coming out against the build-up of the armed forces through mobilization before the beginning of war in view of the difficulty of hiding this undertaking, and consequently, the impossibility of achieving a surprise attack. For this reason it is proposed to have such armed forces in standing combat readiness in peacetime, as they would be able to start military operations without undertaking the slightest noticeable mobilization measures prior to the beginning of armed

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

conflict. It is fully possible that these views are reflected in the aggressive plans of the Command of the Anglo-American Bloc. We have many facts which indicate that this Command, utilizing numerous bases and the territories of the countries dependent on the USA and England, is striving to deploy in advance the necessary groupings of forces and means in the appropriate areas and in the theaters of military operations, from where they plan to start a war against the countries of the Socialist Camp.

Let us pause briefly on the problems which were worked on in the rear area exercises. These exercises took in all the European theaters of military operations. As already noted, in these exercises the existing system for supplying the armed forces of NATO with materiel was checked and the abilities of Bloc member-countries to independently support their troops assigned to NATO were studied.

The following principles were applied as the basis for organizing material-technical support in the exercise. Each member-country of NATO was responsible for the materiel, technical, and medical support of its troops and determined independently the types and quantities of the materiel necessary for the support of combat operations. The commanders of the Allied troops were charged with the responsibility for distribution and use of the material-technical supplies allocated to their jurisdiction, for making up requisitions (together with the corresponding national authorities) for material-technical supplies, and for the fulfillment of these requisitions by the national authorities and by the NATO high command. The commanders of the national formations were responsibile for the materiel, technical and medical support of the troops under their subordination.

Rear support of American and English ground troops was accomplished through zones of communication, which passed through the territories of France, FRG, Belgium, and Holland and were the connecting link between the USA, Great Britain and the zones of combat operations in the Central European Theater of Military Operations. In the aims of -- (part of one sentence missing) -- by rear units -- sectors, the base area (bazovyy uchastok) and the forward area (peredovoy uchastok) within the confines of which were located depots of various designations, rear units and establishments. The command for supplying atomic and missile weapons to the American ground troops was situated in the forward zone; it supplied these types of weapons to all atomic support units, including units assigned under the commands of other NATO

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

members countries.

Motor transport was chiefly used for delivery of supplies; fuel and lubricants were delivered by pipe lines and brought up in tank trucks and RR tankcars. Special attention in the exercise was devoted to questions of rapid delivery of supplies from ports located on the French coast to depots in the zone of combat operations.

As a whole, the system of organization of material-technical support of ground troops in the exercise was characterized by extreme complexity; this was caused by the fact that the governments and commands of each NATO member-country were responsible for supporting their troops with essential supplies, as well as by the differences in the organization of supply of the national formations and troops assigned to the jurisdiction of the NATO Command. One of the vulnerable points in this system is the great extension of the lines of communication. It is sufficient to point out that the depth of the zones of communications of the American and English troops, without counting the depth of the combat operation zones, was more than 700-750 km. This forces the command to subdivide [illegible] into sectors, which in turn complicates the organization of delivery and supply.

There were certain unusual features in the operational calculations of the norms used in the exercise for material-technical supply of the West German ground troops, which consisted of the fact that to facilitate the formulation of estimates, all types of reserves of material-technical supplies were calculated on the basis of unit average norms of supply for one man, expressed in kilograms. Food, clothing, engineer equipment, construction materials, POL, communications equipment and other items were planned in weight units per man.

The method of calculating losses deserves attention. Losses of personnel and combat materiel were determined by taking into account the place of the large unit in the operational formation (mesta soyedineniya v operativnom postroyenii) and the degree of intensity of combat operations. For the first seven days of war these losses were estimated approximately as follows: personnel -14-21 percent; atomic artillery, guided missiles and free rockets, and combat vehicles -30-40 percent; tactical aviation combat aircraft - 71 percent; and air defense aircraft - 53 percent (taking into account repairs of damaged aircraft); atomic weapons - 30-35 percent; conventional ammunition -20-30 percent; POL - 20-35 percent.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Characteristically, losses of personnel, armament, and combat materiel during the first day of war were 3-5 times higher than the average daily losses for the seven days of the war.

The questions worked on in the naval exercise were basically those of defense of communications and control of merchant shipping during the first days of the war. The staffs of the allied naval and air forces on the Atlantic and in the zone of the English Channel, the staffs of the naval forces in the European theaters of military operations, and also merchant marine enterprises of the NATO member-countries took part in this training exercise.

In the design of the exercise it was planned that the main efforts of the NATO naval forces during the first days of the war be concentrated on the annihilation of nuclear missile weapons, airfields and submarine bases in the northwestern and southern areas of ORANGE territory, and on the defense of communications lines in the Atlantic and in the Mediterranean. Prior to the beginning of combat operations mobilization measures were carried out in the naval forces and in the merchant fleet, specific tasks of the allied naval forces in different areas were defined, the dispersion of the forces and weapons of the fleet was provided for, material-technical support and the evacuation of bases and ports were organized, a centralized directorate of shipping was created, convoys were formed and other measures were carried out.

It was considered that with the beginning of military operations a significant part of the NATO naval bases, ports and airfields in Western Europe and in North America was destroyed or was put out of commission for a prolonged period as a result of ORANGE nuclear strikes, and that a part of the reserves of different types of supplies on hand at the beginning of the war in depots of the European member-countries of NATO was wiped out. In this connection, the NATO Command planned to organize loading-unloading work in small harbors, in roadsteads and in unequipped sectors of the coast, although this brought about a decrease in shipping turnover (sudooborot) and a shortage of coasting vessels.

According to the plan of the exercise command, the principal threat to the shipping of NATO member-countries was created by ORANGE submarines, deployed along communications lines in the Atlantic and in the Mediterranean Sea, as well as by their

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

aviation, which along with carrying out attacks against ports and ships at sea, layed mines in coastal communications lines and in the English Channel, the Bay of Biscay and the Mediterranean Sea. In these circumstances, the defense of naval communications was organized on a zonal principle, in accordance with which responsibility for the security of merchant navigation within the boundaries of a theater or region rested on the corresponding NATO naval commander. The guarding and defense of individual vessels which had not yet been brought into a convoy were organized only in areas of most intensive navigation with the use of antisubmarine vessels and aircraft for this purpose, as well as of aircraft carrier antisubmarine hunter-killer groups. With defense of naval communications lines organized in this manner, the NATO Command calculates that the communications lines will not be seriously disrupted at the beginning of the war.

The exercise shows that the NATO Command is devoting great attention to insuring uninterrupted merchant navigation in a future war.

We have examined the most important features of the exercise of the allied armed forces of the aggressive NATO Bloc, SIDE STEP, and the basic problems which were worked on in this exercise. As can be seen, the exercise was a many-sided one, in which many practical problems of preparation and conduct of war in Europe were tested. To a certain degree, the exercise reflects the official views of the command of the Anglo-American Bloc on the nature and methods of waging a future aggressive war against the countries of the Socialist Camp.

Special significance is attached to the advance implementation of mobilization measures to bringing the armed forces to combat readiness, to their deployment in operational formations, and to supplying them with all the essential means of support. The leaders of the Anglo-American Bloc are evidently not certain of the fact that the war unleashed by them will end as quickly as they wish. For this reason they are looking for methods of insuring the readiness of their armed forces even for a war which may be of long duration (last two words uncertain).

In the plans for waging the war the main reliance is placed on the use of nuclear weapons and on the carrying out of a nuclear offensive, with the aid of which it is calculated to drastically

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

change the correlation of forces in their favor and, it is hoped, to give the ground troops the possibility of conducting offensive operations. Among the means of using nuclear weapons side by side with aviation great importance is attached to missiles of operational-tactical designation. At the same time, atomic /barrel/ artillery is widely used as in the past. A large role is also assigned to the ground troops, who are given the mission of exploiting the results of a nuclear offensive for carrying military operations, as may be judged from certain available information, onto the territory of the Soviet Union.

On the whole, exercise SIDE STEP testifies to the aggressive nature of the NATO military preparations, which are openly directed against the Soviet Union and the other countries of the Socialist Camp. It is well to bear in mind, however, that the military preparations of NATO reflected in exercise SIDE STEP do not exhaust all the aggressive plans of the Anglo-American Bloc. As is known, in the future war which they are feverishly preparing against the USSR, the militaristic circles of this bloc place principal reliance on the strategic means of nuclear attack - strategic aviation, intercontinental missiles, missiles of intermediate range, and the aircraft carrier and missile carrier assault fleet. With the aid of these means of armed conflict they aim to solve the main problems of a future nuclear war.

All this obligates our command personnel to study thoroughly the experience of the training exercises of the probable enemy, to analyze more deeply all the measures carried out by them on the preparation and unleashing of a new war against the Soviet Union and the other countries of the Socialist Camp, and to take this into account in the preparation of our armed forces and in the working out of methods of thwarting the aggressive adventures of the NATO leaders.

Intelligence-to the Level of Modern Tasks

by

Marshal of the Soviet Union V. Chuykov

The development of new equipment, the use of nuclear explosives, and of such delivery vehicles as missiles, have confronted military science with one of the urgent problems of the present day -- that of preserving the combat effectiveness of troops. The solution of this problem in almost all the armies of the world takes the form of perfection of the organization of troops and of their technical equipment, of the development of means of antiaircraft defense, of reconnaissance (razvedka) equipment, of methods for the antiatomic protection of troops on the field of battle, and of a number of other measures.

All the types of operational and combat support of troops must be developed and perfected in harmony with the development of the armed forces as a whole. One can have perfect organization of troops, unexceptionable means of controlling them, excellent missile equipment at all levels of the military organism, and strong and mobile means of antiaircraft defense, but if we forget one aspect of troop support, especially the development and perfection of reconnaissance equipment and the issue to intelligence subunits of this equipment, this will immediately influence all spheres of combat activity of troops, and especially that of the use of missile weapons.

Even so important a type of support of the troops as antiaircraft defense will also depend entirely on the ability of reconnaissance equipment to detect targets in good time and to warn the means of combat with the enemy in the air.

Our probable enemies are devoting very great attention to the development of technical reconnaissance equipment at both tactical and operational levels. They are introducing in divisions and armies, on a very wide scale, such reconnaissance equipment as: radar, television, heat sensors (teplolokator), and photographic equipment for ground and aerial photography. From divisional level upwards, all this reconnaissance equipment is available in both ground and aerial versions. Specially equipped aircraft and helicopters have been introduced into the Tables of Organization and Equipment (shtat) of divisions and armored regiments. Intensive work is being conducted on the evolution of pilotless equipment for aerial tactical and

[redacted]

1.3(a)(4)

1.3(a)(4)

[redacted]

1.3(a)(4)

operational reconnaissance. Several modifications of pilotless equipment for aerial reconnaissance have already been developed and tested.

In the armies of the North Atlantic bloc countries, no less serious attention is devoted to the training of intelligence units for reconnaissance and diversionary operations in the rear of our troops. Thus, in the armies of Great Britain, intelligence regiments specially assigned to the conduct of reconnaissance against the disposition of our troops have been introduced into the composition of an army corps.

NATO member-countries must include in the composition of their divisions assigned to the allied armed forces, reconnaissance equipment which is capable of performing reconnaissance tasks against objectives which are liable for destruction by nuclear weapons.

The development and improvement of reconnaissance equipment will permit more successful use of missile units and of aircraft to combat the enemy's means of nuclear attack. Attention must therefore be paid to reconnaissance not only as a type of combat support for the troops in the development of theoretical situations at command-staff and troop training exercises; it is mainly necessary to possess the necessary reconnaissance forces and equipment during peacetime and to prepare and perfect them carefully.

In actual fact, how do our present army and division intelligence subunits differ from those of the Second World War? The difference lies only in the fact that amphibious tanks and armored carriers have been brought into the composition of the intelligence subunits of divisions and armies, as a result of which these subunits have acquired great mobility. However, just as there was previously no technical reconnaissance equipment in intelligence subunits, there is still none today. The Tables of Organization and Equipment do not provide intelligence subunits with equipment for optical reconnaissance, or with infrared equipment, heat sensors, or other technical reconnaissance equipment.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It should be noted that the technical reconnaissance equipment of a front has not experienced any fundamental changes. Agent networks and radio and radiotechnical reconnaissance, with the exception of aerial reconnaissance, are not capable of carrying out reconnaissance tasks for the missile troops with the necessary precision in determining the location of the target in a particular area.

It must be admitted with complete frankness that modern reconnaissance equipment, in the form in which it appears organizationally and in the way in which it is technically supplied, has lagged far behind the level of development of weapons of destruction. Without belittling the role or the significance of tried reconnaissance equipment or of its methods of operation, one can say without exaggeration that this equipment can no longer fully meet the tasks imposed on reconnaissance in furnishing missile units with intelligence data.

Existing divisional and army intelligence subunits (units) permit the organization of reconnaissance by observation, at best, with the help of ordinary binoculars, by the execution of raids and ambushes, and during combat by the dispatch of a reconnaissance detachment or of separate reconnaissance patrols whose range of operation is limited by the capabilities of existing means of communication which may reach 30 kms, which is obviously insufficient. Under the most favorable terrain and weather conditions the artillery reconnaissance equipment of a division and of an army can carry out reconnaissance to a depth of 10 to 15 kms, and, with their help, it is possible to obtain information on mortars, field artillery, the movements of the enemy, and the progress of engineering works, but only up to the limits of direct visibility.

We venture to assert that the function of the intelligence service is not valued highly enough by us; were this not the case, there would not be so vast a gap between the capabilities of weapons of destruction and of those of reconnaissance equipment.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It is necessary to remember that in many respects modern operations will differ from those of previous wars. Some of the special features of these operations, it may be assumed, will consist of the tendency of both sides to carry out continuous combat operations directed, first of all, at the destruction of the means of atomic attack both on the ground and in the air; the destruction of the means of atomic attack before they are used will result in unprecedented reconnaissance activity by both sides with the goal of not only locating these means but of destroying them by all possible sabotage methods, both during the period of preparation and during the actual course of the operation.

The constant threat of destruction by nuclear weapons will result not only in the maximum possible dispersal of troops in areas of disposition but also in the carrying out of combat operations in broader zones.

No one will deny that the preservation of the combat effectiveness of troops in modern conditions, and consequently the successful execution of any operation, and especially the use of missile units, will, to a marked degree, depend upon the timely performance of the following tasks:

-- acquiring knowledge of the grouping of delivery vehicles for nuclear warheads and, equally, of the plants producing fuel components, of assembly bases and warhead storage depots;

-- acquiring knowledge of the control and guidance systems of guided missiles and pilotless weapons;

-- immediate destruction of the means of nuclear attack, without timing this to coincide with specific operational-tactical periods.

With existing technical reconnaissance equipment, neither a division nor an army can perform the tasks listed above, because they do not have at their disposal sufficient personnel and, even more, enough reconnaissance equipment. There is now a tendency toward the reduction in force of intelligence subunits

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

which have already been reduced to the maximum. We have not a single organ, even at the center, which is working on the problems of the technical equipment of intelligence subunits at the tactical and operational level.

One asks how the commander of an army or the commanding officer of a division who lacks the most essential intelligence information and the equipment necessary to obtain this information can make well-founded decisions and utilize successfully his own means for the destruction of the enemy's means of atomic attack?

With the existing organizational structure of military intelligence, almost all the technical reconnaissance equipment which is capable of obtaining information on nuclear weapons is basically present at a front. The tasks of annihilating means of nuclear attack will be decided on by the commanding officer of a division and by the commander of an army. Hence, in the very organizational structure of the intelligence organs there is a rift between intelligence assets and the command echelons which organize the immediate fulfilment of important operational and tactical tasks.

The lack of technical reconnaissance equipment in a division, corps, and even an army during the Second World War resulted in the fact that these echelons solved the majority of the intelligence tasks by requests to higher headquarters. Thus, a division forwarded its requests for intelligence to a corps, the corps to an army, and [4 or 5 words missing].

The principle of solving intelligence tasks by means of requests to higher headquarters has outlived itself long ago and is obviously not suitable in modern conditions. Firstly, it impedes the activation of all intelligence assets at division and army level; secondly, and this is most important, it impedes the development and introduction of modern technical reconnaissance equipment into a division and an army; thirdly, this principle has become a cover for inactivity by subordinate headquarters in the problems of organization and of carrying out reconnaissance.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The limited availability of intelligence personnel and equipment and the eagerness of commanding officers at all levels to receive intelligence information on objectives of direct interest to them in the shortest possible time, makes it urgently necessary to make the concept of the prospective operation (battle) the basis for the organization of reconnaissance, in order to ensure that all available intelligence personnel and equipment are used in the most purposeful manner from the beginning to the end of the operation (battle). Such purposeful use of intelligence personnel and equipment can be determined only by the commander (commanding officer) who has detailed knowledge of the intention and plan of the prospective operation and battle.

Regrettably, there are still commanding officers of divisions and commanders of armies who do not allot proper significance to intelligence problems, who farm out all the work pertaining to intelligence organization to the intelligence chiefs, which brings about a lack of purposefulness in intelligence.

In order to accomplish the tasks of discovering the grouping of the enemy and especially of his nuclear weapons, it is necessary to have strong, technically well-equipped intelligence subunits at division and army level which are capable of performing tasks which are within the range of their own means of destruction. The need for the availability of a variety of technical and other reconnaissance equipment in a division and an army is also expressed by the fact that information obtained from one source should not be considered as reliable until it is confirmed from two or three sources.

At the present time statements of opinion are appearing in periodicals on the formation of some type of joint centers for the utilization of reconnaissance equipment, for the collection and processing of intelligence data, of fire delivery centers and, about the endeavor to provide more reliable communications for all intelligence organs of the front with artillery headquarters, etc. All of this appears to be linked with the noble intention of finding ways to resolve the basic problem -- the reconnaissance of the means of nuclear attack and the provision to the missile units of targets for destruction. However, this has nothing in common with the problems of intelligence organization. The

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

resolution of the problems of intelligence organization and the acquisition of intelligence data should be sought not by the creation of some type of improvised centers, but by the correct distribution and structural organization of reconnaissance assets able to perform intelligence tasks for a division, an army, or a front, and also in the centralized utilization of the reconnaissance equipment of the arms of troops.

The real centers for the organization of intelligence must be combined-arms staffs in the form of intelligence sections, departments, and directorates (otdeleniye, otdel i upravleniye). However, in order not to exclude the chiefs of other arms of troops from the intelligence system, provision must be made for an organizational structure in the composition of these arms of troops, with intelligence equipment capable of performing intelligence tasks for the given arm of troops.

The approximate layout of the organization of intelligence should be as follows. The combined-arms staff, with the active participation of the arms of troops, organizes reconnaissance, collects, analyzes, and collates all intelligence data. On the basis of a thorough analysis it determines the general grouping of nuclear means, the grouping of tanks, the means for control of nuclear weapons, and the grouping of the pilotless weapons and aircraft of the enemy. On the basis of this information, the commander (commanding officer) decides on the execution of the operation (battle). The chiefs of arms of troops, having received specific tasks and targets for destruction, study these targets together with the divisional, army, and front intelligence chiefs before delivering the strike, and organize additional reconnaissance of the objectives (targets) with their own and with the combined-arms assets. From this it follows that in the combined-arms staff a single intelligence plan must be developed which provides for the use of all the intelligence personnel and equipment of the arms of troops. Specific intelligence tasks, such as: the topographic and geodetic work of the artillery, engineer reconnaissance of terrain, of the passability of roads, etc., must be reflected in great detail in the intelligence plans of the appropriate arm of troops. In our opinion, such a principle of organization and execution of intelligence will permit the tasks of reconnoitering those objectives of the enemy which are liable for destruction by nuclear weapons to be fulfilled more successfully.

Conditions for the conduct of modern operations urgently demand a most attentive and serious review of the organizational structure

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

of military intelligence organs from top to bottom.

The idea of providing command echelons with reconnaissance equipment in accordance with the tasks levied on any particular troop element must be implanted in the organizational structure of the intelligence organs. Therefore, in the composition of an army and a division, it is necessary to have reconnaissance equipment that could obtain data of interest to the commander of the army and the commanding officer of the division. This necessity results from the fact that the role of armies in modern operations and, correspondingly, the role of the division in a battle, has increased. The modern army (combined-arms and tank) is capable of the independent performance of operational tasks concerned with the destruction of the enemy in wide zones and to a great depth, and of the conduct of combat against the enemy's means for nuclear attack. The absence from an army (combined-arms and tank) of organic (shtatnyy) reconnaissance equipment puts the army commander and the army headquarters into a position of dependence upon the front headquarters, and this paralyzes their initiative in questions of the conduct of combat against the nuclear means of the enemy.

The high mobility of the use of nuclear weapons (as a rule there will be only one firing from each position) calls for a highly mobile means of reconnaissance. Today such a means is aerial reconnaissance, which is capable of penetrating enemy positions to a great depth, and of obtaining in a brief period of time the most reliable documentary (dokumentalno-podtverzhdayemyy) intelligence data on sizeable areas.

For this reason, the composition of combined-arms and tank armies must include organic means for tactical aerial reconnaissance. These must be capable of performing a great number of tasks, for example, of carrying out visual reconnaissance by day and night, of taking aerial photographs of objectives (areas) and of correcting the fire of the army's artillery. Aerial reconnaissance in support of the army must be carried out to a depth of not less than 200 kms. Reconnaissance aircraft must carry one-step photographic processing equipment capable of independent processing of the results of aerial reconnaissance directly in the aircraft in order to shorten to the minimum the time needed for processing and montage. In our view, in order to perform the tasks indicated, a combined-arms or tank army must have in its composition a tactical aerial reconnaissance regiment /3 or 4 words missing/.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The means of radiotechnical intelligence are mainly concentrated at the front. Combined-arms armies have very weak radio intelligence companies, while tank armies have none at all. Radiotechnical intelligence can obtain highly valuable data on enemy troop groupings, on his posts and radar means for guiding missiles, pilotless means, and aircraft. On the one hand, the fact that radiotechnical intelligence equipment is available only in the front significantly reduces the potentialities of radio intelligence, since the front's means are not capable of intercepting tactical, operational, and aircraft radio nets, and on the other hand, because the transmission of radiotechnical intelligence data to an army, and also, occasionally, to a division, requires much time.

Because of this, the need has grown for a substantial improvement in the radio-and radiotechnical intelligence of an army in order that the latter may perform the tasks of uncovering radio nets from battle group to field army level inclusive, and the radar stations of guided-missile subunits and the control centers and posts of his pilotless weapons, and of the tactical aviation located in the tactical and immediate operational depth. For the performance of these tasks it is necessary to introduce an OSNAZ (osoboye naznacheniye-special designation) radio battalion into the composition of an army (combined-arms and tank) and to give it organizational strength. Such a radio battalion should be equipped with more highly-perfected radio and radiotechnical equipment with good protection against jamming, which should be mounted on mobile means with good cross-country ability.

In order to improve the capability of an army's long-range radio intelligence surveillance of ultra-shortwave and radio-relay nets, helicopters equipped with radio reception and tracking (priyemo-slezhechnyy) apparatus are needed in the composition of OSNAZ radio battalions.

The presence of breaches, gaps, and exposed flanks in the operational and tactical disposition of enemy troops creates conditions for the deep penetration of the enemy's positions by strong reconnaissance detachments with the aim of reconnoitering the approaching reserves of the enemy and of his nuclear means, with the destruction of the latter. To perform reconnaissance

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

tasks against exposed flanks and breaches and for penetrations into the deep rear areas of the enemy with the aim of reconnoitering and destroying means of nuclear attack, it is desirable to bring a reconnaissance regiment into a combined-arms army, and to retain it in a tank army. It is desirable to have reconnaissance battalions in motorized-rifle and tank divisions.

The reconnaissance regiment of a combined-arms and tank army must have a uniform organization, and must include in its composition no less than three reconnaissance battalions: two battalions to carry out reconnaissance as reconnaissance detachments and one battalion to carry out reconnaissance in depth. Reconnaissance battalions, in their organization, armament, and equipment, must be capable of the independent performance of reconnaissance tasks both as whole battalions and by companies, as well as by platoons, at a considerable distance from the main forces of the first echelon of the army. As regards firepower, the armament of the battalions must be powerful and mobile, and the tanks must be equipped with perfected equipment for underwater operation.

Troop exercises have shown that groups specially trained for reconnaissance in depth are a most valuable source of intelligence data on enemy means of nuclear attack. A deep reconnaissance battalion should provide, from its own composition, for the formation of 30 to 40 reconnaissance groups. The presence of such a battalion in the composition of an army will provide for reconnaissance of the enemy's means of nuclear attack up to a depth of 100 kms.

In the composition of a regiment there must also be suitable communications facilities to ensure the control of deep reconnaissance groups and of the reconnaissance detachments of the army to a depth of not less than 100 kms. The composition of an army must include aircraft and helicopters specially designated to land deep reconnaissance groups in the enemy's rear area. The technical equipment of the helicopters must enable them to make night landings on unprepared terrain.

The need for effective reconnaissance equipment in a division is dictated by the fact that a divisional area of advance of up to 12 kms is already established by the Field Service Regulations.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The possibility that a division will operate on even broader areas in the future is not excluded. Under these conditions, a division will have to perform independently numerous reconnaissance tasks such as: reconnaissance of the enemy's tactical nuclear weapons; discovery of his troop groupings and of the nature of his defense in tactical depth; reconnaissance of water barriers for the purpose of enabling tanks to cross on the bottom, and a number of other tasks. To perform the above-mentioned tasks, the reconnaissance battalion of a division must have in its composition not less than two reconnaissance companies, a deep reconnaissance company, an engineer-chemical and radiation reconnaissance platoon, a communications platoon, and a maintenance subunit.

A reconnaissance battalion must be capable of carrying out reconnaissance both in companies and in platoons, and groups equipped for movement away from roads and able to force water barriers without additional crossing equipment. Under modern conditions these demands are best met by amphibious tanks and combat reconnaissance patrol vehicles (boyevaya razvedyvatelnaya dozornaya mashina - BRDM) which have high cross-country ability over any terrain and which can pass any water barriers. The armament of a battalion must not impede its mobility. It must be equipped with recoilless weapons and machine guns mounted on BRDM's, i.e., the armament of each individual battalion and company must enable it to engage in a brief battle with a high volume of fire in the interests of reconnaissance. Battalion subunits must be equipped with the requisite optical, infrared, and lightweight radiotechnical means of reconnaissance.

The reconnaissance equipment of a front element (zveno) should consist primarily of technical means and of a competent agent net capable of performing intelligence tasks throughout the entire depth of the front's offensive operation. The organizational structure must ensure that intelligence data are rapidly collected, processed, and transmitted to interested commanding officers and troops without passing through unnecessary intermediate channels.

For the performance of a large number of reconnaissance tasks in the discovery of means of nuclear attack and for the carrying out of continuous additional reconnaissance of targets already detected, it is desirable to have in the composition of a front

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

one or two regiments of operational, and one regiment of tactical, aerial reconnaissance. In the composition of each regiment of operational reconnaissance there should be squadrons of day and night photo-reconnaissance and infrared equipment. The need for night reconnaissance in each regiment is due to the fact that troop regroupings and the occupation and shift of firing positions of the means of atomic attack will be carried out by the enemy primarily during the night.

For the allocation of tasks and the control of aerial reconnaissance assets, it is necessary to have an aerial reconnaissance department in the intelligence directorate of a front headquarters.

To process the results of aerial photography, instead of a temporarily established center for photo-interpretation at the intelligence directorate of a front, there should be an appropriate number of photo-interpretation officers in the operational reconnaissance regiments capable of carrying out the operational and tactical photo-interpretation of targets and of determining their coordinates.

At present, aerial radiotechnical reconnaissance equipment is located at the air army and in the radiotechnical regiment (OSNAZ) of a front. To centralize the control and processing of intelligence data, it is advisable that this equipment should be concentrated in the radiotechnical regiment (OSNAZ) with 12 to 15 radiotechnical reconnaissance aircraft, which will enable it to conduct reconnaissance on a 24-hour basis to a depth of 400-500 kms. The radio intelligence (OSNAZ) regiment of a front should be left at its present composition.

For the conduct of intelligence collection against enemy means of nuclear attack and nuclear weapon storage depots located in the operational depth, and for their destruction, it is advisable to have one or two battalions of special designation in a front. With the goals of acquiring experience and of creating reserves of intelligence officers, it is necessary, even in peacetime, to have a company of special designation in the composition of a military district.

[redacted]

1.3(a)(4)

The experience of troop, staff, and special intelligence exercises shows that in modern short-duration forms of combat, the control of reconnaissance equipment, the timely collection of intelligence information, and its dissemination to subordinate headquarters and troops assume very great significance. Maintenance of communications with the reconnaissance organs by command and headquarters networks is not always possible. In such cases, much time is expended in the receipt of intelligence data, and consequently the value of these data is partially lost. A need has therefore arisen for the creation of special intelligence communication nets, providing communications with reconnaissance organs which have been dispatched, with the chiefs of intelligence of subordinate staffs, and with deep reconnaissance groups and reconnaissance aircraft. In order to ensure stable communications with all reconnaissance organs it is necessary to have the requisite communications equipment, which should be included in the Tables of Organization and Equipment of divisional, army, and front communications units.

It is especially desirable to stress that our troops do not yet have radio sets which are light-weight, compact, rapid and of high-speed operation (bystrodeystvuyushchiy), ensuring the stable communications which are so necessary in providing communications with deep reconnaissance groups; this significantly impedes the operations of the groups and the maintenance of communications with them.

In our view, the realization of all these measures will permit more efficient use of all reconnaissance equipment, timely receipt of intelligence data, and more successful utilization of modern means of warfare.

SUBJECT : MILITARY THOUGHT (TOP SECRET): "The Fundamentals of Antimissile Defense", by Colonel-General of Aviation I. Podgornyy

DATE OF INFO : December 1961

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Fundamentals of Antimissile Defense", by Colonel-General of Aviation I. Podgornyy.

This article appeared in the 1962 First Issue of a special version of the Soviet military journal Voyennaya Mysl (Military Thought). This journal is published irregularly and is classified TOP SECRET by the Soviets. The 1962 First Issue went to press on 29 December 1961.

Headquarters Comment: Military Thought is published by the USSR Ministry of Defense in three versions, classified RESTRICTED, SECRET, and TOP SECRET. The RESTRICTED version has been issued monthly since 1937, while the other two versions are issued irregularly. The TOP SECRET version was initiated in early 1960. By the end of 1961, 61 issues of the SECRET version had been published, 6 of them during 1961.

The Fundamentals of Antimissile Defense

(From foreign sources)

Colonel-General of Aviation I. Podgornyy

Under the conditions of a nuclear/missile war, reliable antimissile defense, as a factor of strategic significance, is becoming one of the most important conditions for the successful conduct of a modern war.

The development of defensive weapons takes place in dialectical unity with the development of attack weapons. A comprehensive study of the characteristics, potentialities, and direction of the future development of ballistic missiles must be the basis for the correct resolution of questions of the organization of combat against ballistic missiles.

The basis of an aerial attack on objectives of the country consists of attack weapons of strategic designation, which in the USA are divided into three basic groups in accordance with their flight-technical characteristics:

-- aerodynamic aircraft;

-- ballistic missiles;

-- cosmic devices.

The second group is the most promising and rapidly developing. Here the main efforts are being directed toward the production of long-range missiles as the main striking force. The share of missiles' participation in the performance of the tasks of aerial attack will increase with every year, and in the near future, the ballistic

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

missiles in the enemy's arsenal of attack weapons will assume the leading role. The armed forces of the USA are equipped with ballistic missiles of various classes and various ranges of operation. The intercontinental missiles, "Atlas", "Minuteman" and "Titan", are intended for delivering strikes against objectives located at a distance of 10,000 to 16,000 km, the intermediate-range missiles, "Jupiter", "Thor" and "Polaris", - for objectives located up to 2,000 to 3,500 km away and the short-range missiles, "Pershing", "Redstone", and others - against objectives at a distance of up to 350 to 550 km.

In the USA work is being conducted on the creation of ballistic missiles of the "air-to-surface" class. Specifically, it is intended to arm the B-52, "Victor", and "Vulcan" strategic bombers with a missile of this class, the "Sky Bolt".

At the present time the strategic missile attack weapons of the potential enemy are deployed in the continental part of the USA, and also on the territories of their allies in the aggressive blocs. In the USA, 65 launching sites for intercontinental ballistic missiles have already been built; by 1965 it is planned to increase their number to 860 launching mounts. On British and Italian territory there are 90 intermediate-range missile launching sites deployed; the construction of 15 launching sites is being completed in Turkey. There are 5 atomic submarines armed with "Polaris" missiles on combat patrol.

Thus, an analysis of trends in the development of weapons of strategic attack and in the proposed deployment of the probable enemy's missile bases permits one to conclude that in the future the basic means of strategic attack will be intercontinental ballistic missiles deployed on the territory of the United States of America, and intermediate-range missiles, the launching sites of which are located around the Soviet Union and the countries of the

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

peoples' democracies.

Missile-carrying submarines, missile-carrying aircraft, and strategic bombers will be the maneuverable weapons.

An effort to use force against the elements that make up the national might of the probable enemy is the basis of the official American aerospace doctrine. The first task of aerospace operations is undermining the nuclear/missile might of the Socialist Camp in order to disrupt or weaken to a significant degree the strength of our missile strikes. Simultaneously with the performance of the main task, it is planned to deliver strikes against the most important administrative-political and military-industrial centers and other objectives, with the goal of disorganizing the control of the country, disrupting the mobilization of troops, and undermining the military-economic potential and morale of the people. A nuclear/missile attack must be massive, and be carried out using the element of surprise and in a short period of time. It should be assumed that the most powerful first ballistic missile strike will be organized so that the missiles of various ranges of operation will enter the zone of detection of the antimissile defense means at the same time.

For this reason the antimissile defense can successfully perform its tasks if its structure takes into consideration a capability for repulsing the first nuclear/missile strikes of the initial period of war which are carried out by the enemy with the use of various countermeasures directed toward reducing the effectiveness of the defensive weapons.

The nature of nuclear/missile war, with its decisive goals and unprecedented spatial scope, makes antimissile defense the most serious task of the present day.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

Success in combat with ballistic missiles can be achieved by the joint efforts of all types of armed forces. Disruption of enemy nuclear/missile strikes can be accomplished by destroying ballistic missiles which are ready for launching on launching sites, as well as by destroying them in flight.

We understand antimissile defense (PRO) (protivoraketnaya oborona) to be one of the methods of armed combat, directed toward the protection of the country and its armed forces from an enemy missile attack by means of destroying ballistic missiles in flight.

Combat with ballistic missiles in flight is a complex military-technical problem. In order to realize all its difficulty it suffices to say that in PRO it is necessary to deal with insignificant targets, as far as size and reflecting surface are concerned, flying at enormous altitudes and at cosmic speeds. Thus, for example, the nose cone of an "Atlas" missile, in the centimeter wave band, has a reflecting surface of about 0.5 square meters, a maximum flight speed of more than 25,000 km per hour, and a maximum height of the trajectory of 1,300 km.

This problem can be made even more complex by the enemy if a series of measures that complicate detection, interception and destruction in flight are taken into consideration:

1. The launching of ballistic missiles under quadrant angles of departure that are less than the optimum, which leads to a reduction in the range of detecting them by the means of the PRO.

2. The employment of dummy targets which lower the probability of destruction of the nose cones of the ballistic missiles.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

3. The reduction of the reflecting surface of the nose cones of the ballistic missiles by using various materials that absorb radio signals.

4. The use of special transmitters for creating active interference with the PRO radiotechnical equipment, including those that are located in the nose cone of the ballistic missiles or are ejected in containers.

Based on the nature of antimissile defense, the tasks of PRO are:

-- detection and recognition (raspoznavaniye) of ballistic missiles;

--destruction of ballistic missiles in flight;

-- immediate warning of the military command and the civil defense of the start of an enemy missile strike;

-- detection of artificial earth satellites.

Antimissile defense as a whole, like anti-air defense, must satisfy a series of requirements, the basic ones of which are constant readiness to repel an enemy missile attack, high effectiveness and stability.

Consequently, the construction of antimissile defense must be carried out simultaneously in two interrelated directions. One of these is the creation of a system of means for combatting ballistic missiles in flight, the other is the elaboration of the theoretical principles of employment, combat utilization and organization.

In principle, the destruction of missiles is possible both in the initial, active sector of the flight and in the final sector of the trajectory.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

However, research shows that at the present time, the creation of means of antimissile defense capable of destroying missiles in the passive sector of the flight, before entry into the dense layers of the atmosphere, is most realistic.

In the opinions of foreign specialists, at the present time an antiaircraft missile complex specially created for antimissile defense, with a guided antimissile missile can be an effective means for combatting ballistic missiles. Such an antimissile complex must:

-- detect the ballistic missile at a considerable distance from the area being covered and determine the elements of the trajectory of its flight;

-- pick out the nose cone against a background of dummy targets;

-- carry out the placing of the antimissile missile on the plotted flight trajectory of the ballistic missile and secure, with the necessary accuracy, the approach of the antimissile missile to the nose cone;

-- destroy the nose cone of the ballistic missile.

The total time during which an antimissile complex must fulfil its mission is only a few minutes; therefore all its operations must be fully automated. From the technical standpoint the PRO complex must be an aggregate of radar sets, ground equipment, the control system, the antimissile missiles, and computing devices.

The structure of the organization of combat with ballistic missiles may be examined from the example of the "Nike-Zeus" antimissile system that is being developed in the USA.

6. Complex of electronic-computing equipment;
7. Launching site of the antimissile missiles.

IV - Area defense center with an electronic-computing equipment complex.

In preparing a new world war, along with the development of new weapons of attack, American imperialism has in recent years been increasing work on the creation of means of antimissile defense. In this field efforts are exerted in two directions: the creation of an early warning system capable of ensuring ultra long-range detection of intercontinental ballistic missiles in flight and the creation of a complex of active PRO means capable of destroying a missile warhead.

Scientific-research work on the creation of active PRO means began in 1952 in the USA. As a result, plans for several systems were worked out; however, with the exception of the "Nike-Zeus" system, work on all the remaining plans was stopped. The basis of this system is composed of a battery of antimissile missiles, the unit of equipment for which includes: a target recognition radar set, a target tracking radar set, an antimissile missile tracking

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

radar set, an intercept computing device, control equipment, launching mounts, and auxiliary equipment.

It is intended that control of the fire of several batteries be carried out from a so-called area defense center that is equipped with a target designation radar set and a computing device, the function of which is the processing of data on detected targets, and target designation for the batteries.

The organizational structure of the subunits of the system is still in the study stage, it is intended to have several antimissile missile tracking radar sets in a battery, which will permit the carrying out of several simultaneous guidance operations against one target.

The sequence of the work of the basic elements of the "Nike-Zeus" system in destroying the nose cones of ballistic missiles is as follows:

According to the early warning system's data, the target designation radar set detects the nose cone of the ballistic missile, and the computing device of the area defense center, on the basis of these data, carries out target distribution and target designation for the antimissile missile batteries. The set works in a pulsed mode. Because of its great power (up to 50 megawatts per impulse) it has separate transmitting and receiving antennas placed up to 300 meters apart. In order to ensure protection of the personnel from radiation, the transmitting antenna is enclosed by a screened metal shield with a height of 20 meters. The maximum range of operation of the set is 1600 km. The time available for reliable detection of the target and for determining its parameters is about 20 seconds.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

The antenna of the recognition radar set, located in the fire complex, is aimed according to the target designation data.

The need to use such a set is brought about by the peculiarities of protecting the system from passive interference and dummy targets outside the dense layers of the atmosphere, where they have the same high speed as the nose cone of the missile.

At the present time the set is in the stage of development (dorabotka), in the process of which it is planned to use the results of the work on the "Defender" program, specifically the study of the electromagnetic characteristics of the nose cones of ballistic missiles. It is planned that the recognition set will work in the decimetric wave band and have an operating range of about 1,000 km.

After separating the real target from the group of dummy ones it switches over to the target tracking radar set, which is designated for automatic tracking of the missile nose cone and processing of the data necessary to determine the calculated point of impact and the commands for guiding the antimissile missile to the target.

Using a parabolic reflector with a diameter of 7 meters, the antenna system of the set creates a narrow pencil-like beam, which is necessary for a high degree of accuracy in determining continuous coordinates of the target. The operating range of the acquisition and tracking (soprovozhdeniye tseli) radar set is about 1,000 km.

The antimissile missile tracking radar set is designated for the automatic tracking of the antimissile missile, for processing the data necessary for guiding it to the target and for transmitting guidance commands and commands for

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

detonating the warhead of the antimissile missile. In order to simplify tracking of the antimissile missile, a radar responder is installed on board.

For intercepting and destroying the nose cone of a ballistic missile, the "Nike-Zeus" antimissile missile is used; it is a three-stage wingless missile 14.7 meters long and has a launching weight of 10,400 kg. The booster of the antimissile missile, which operates on solid fuel, develops a thrust of about 200 tons. The antimissile missile has a maximum altitude of 150 km, a range of 320 km and a maximum speed of up to 2,600 m/sec. These performance characteristics are obtained both by the booster and by the powerful solid fuel sustainer motor. All the missile-borne control equipment is located in the casing of the third stage of the missile. Control of the flight of the antimissile missile in the atmosphere is carried out by means of external rudders (aerodinamicheskiy rul'), and at great heights it is carried out by means of jet nozzles.

The warhead of the antimissile missile may be equipped with both ready-made (gotovyy) destructive elements and with a nuclear charge.

Destruction by ready-made elements occurs as a result of a mechanical effect on the nose cone of the ballistic missile. The nature of the destructive action of a warhead with a nuclear charge depends on the altitude at which it is employed. At heights of up to 40 km the basic destructive factor is the energy of the shock-wave; at greater altitudes it is the energy of various types of radiation, mainly neutron and roentgen.

According to data from the foreign press, total expenditures of the USA on the development of the "Nike-Zeus" system have exceeded 1 billion dollars;

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

however the question of developing the production of the system has been postponed until the end of its testing program. American specialists consider that the tremendous success of the Soviet Union in the field of missile technology permits it to have any missiles required with appropriate devices and to outstrip the employment of countermeasures in a PRO system. Therefore a correct understanding of the potentialities of the PRO system may be grasped only after carrying out test firings against ballistic missiles that create dummy targets and other interference.

* *

*

In order to repel a massed missile attack, a system of antimissile defense that is organized in advance and built according to a single plan on the scale of the entire country is necessary. The theoretical bases for constructing an antimissile defense are the foundation on which a PRO which gives the maximum effect with the minimal expenditure of forces and means must be built.

In constructing a system of antimissile defense, the nature of employment and the technical characteristics of the enemy's ballistic missiles, the combat capabilities of antimissile weapons, the quantity and nature of the objectives to be defended, and also their location in relation to the probable axes of missile approach exert the determining influence.

If we take the Soviet Union, then the probable axes of missile approach for it at the present time are the northern, from the USA, and the western, from Britain and Italy. 1.3(a)(4)

[redacted]

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

In conformity with the individual objectives of the country, specific sectors can be allotted on the probable axes of missile approach, within the limits of which the appearance of ballistic missiles of the probable enemy may be expected. These sectors are the determining factors in creating antimissile defense of objectives or groups of objectives. However, when determining probable axes and sectors of missile approach, the possibility of an attack with ballistic missiles of various classes, launched both from missile bases and from submarines and missile delivery aircraft, should be taken into consideration.

The structure of antimissile defense must provide for the interception of missiles not lower than the specific altitude at which the burst of the nuclear charge will be safe. Calculations show that for the safety of objectives of the country, when intercepting intercontinental missiles and intermediate-range missiles, the altitude of the destruction of their nose cones must be not less than 40 to 50km, and when considering the use of nuclear charges with a TNT equivalent of 7 to 10 megatons - not less than 80km. For short-range missiles. whose TNT equivalent does not exceed 1 megaton, the altitude of interception should be not less than 15km. Consequently the fire complexes must ensure destruction of the warheads of ballistic missiles at altitudes not lower than those indicated.

The defensive zones of the fire complexes exert a decisive influence on the structure of antimissile defense.

We consider the defensive zone of a PRO fire complex to be that part of the territory that is covered by the given complex. It represents the geometrical location of the possible points of impact of ballistic missile nose cones, the trajectories of which pass through the destructive zone of this fire complex.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

The size of the defensive zone of the fire complex essentially depends on the angles of fall of the ballistic missiles, and its orientation depends on the direction of firing (diagram 2).

There is a definite part of the territory that is covered by the fire complex irrespective of what are the angles of fall and from which directions the ballistic missile firing is being conducted. This part of the territory may be called the internal defensive zone.

The objectives located in this zone will be covered under any angle of fall and direction of fire; the remaining objectives located within the limits of the external defensive zone of the fire complex will also be covered, but only for certain angles of fall and directions of fire.

Obviously, by means of appropriate deployment of the fire complexes, the screening of an area that is considerable in size may be carried out. In this, the grouping of the complexes must be such that the important objectives of the area are definitely located with the limits of the internal zone.

The grouping of the PVO means must be sufficiently effective to repel massed missile strikes delivered simultaneously against a series of objectives. For this the number of fire complexes defending objectives or groups of objectives must be no less than the number of targets expected to be operating simultaneously against the given objective or groups of objectives.

In creating fire groupings, covering of the defensive zones of the fire complexes of contiguous groupings should be provided for, in order to create an overall defensive zone for all objectives located in the given area.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

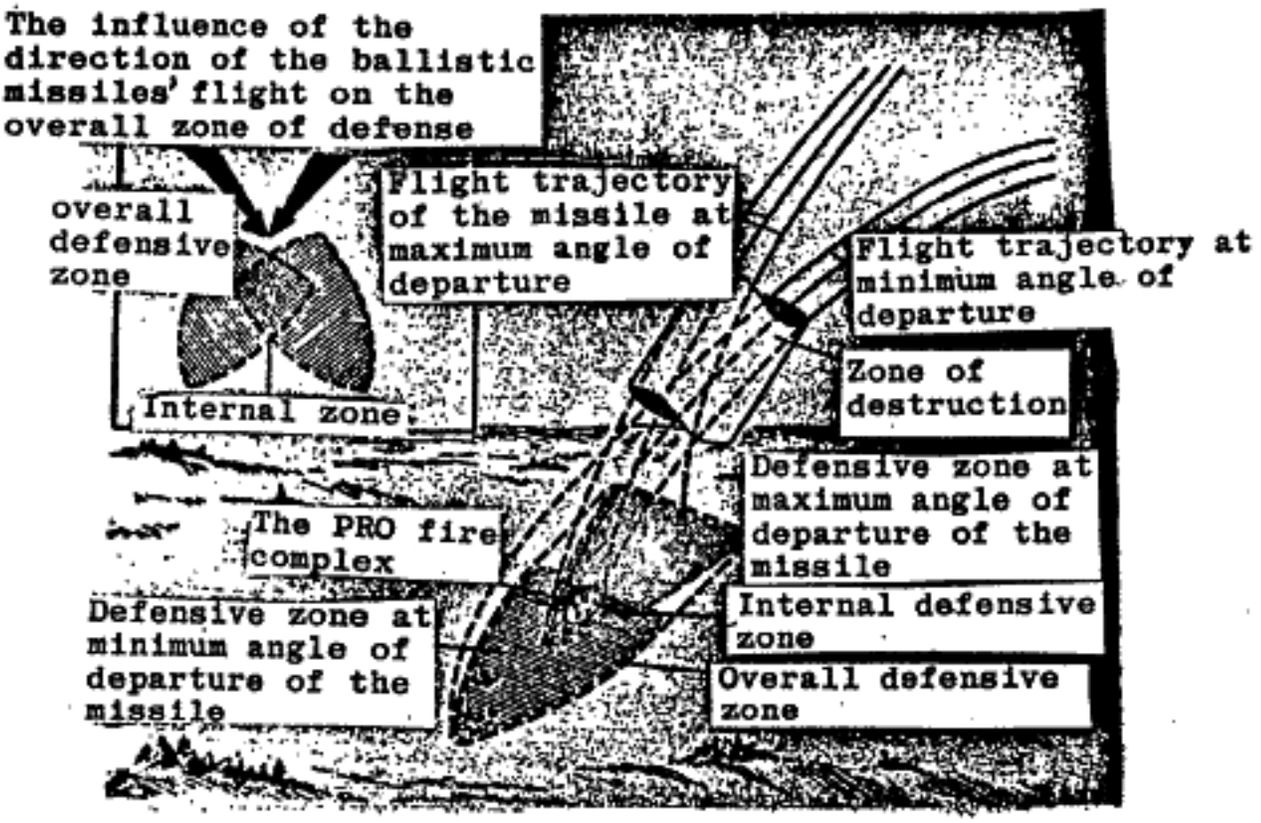

Diagram 2. Defensive zone of the PRO fire complex.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

IRONBARK

[redacted]

1.3(a)(4)

The advisability of this formation is determined by the fact that, first, it permits concentration of the efforts of a series of groupings in repelling a strike by missiles whose number may exceed the fire capabilities of a grouping taken by itself; secondly, with a relatively smaller number of weapons it is possible to cover a larger number of objectives of various categories.

A system of antimissile defense, it appears, should be based on the use of antimissile weapons of several types, the basic ones of which may be:

- weapons intended for screening individual areas from intercontinental ballistic missiles and intermediate-range missiles; possibly these same weapons may also be enlisted for destroying artificial Earth satellites in low orbit;

- weapons intended for screening individual objectives from short-range ballistic missiles, mainly for the defense of frontier and maritime objectives.

Concerning the interception of artificial Earth satellites in high orbit, for this it is apparently necessary to have other fire weapons having a great range of operation. However, the radar support of the antispace defense fire weapons can be retained by the antimissile defense.

The need to employ two types of antimissile weapons is stipulated by the fact that the weapons intended for combat with intercontinental and intermediate-range missiles cannot be employed to destroy short-range missiles.

The small ranges and flight time of operational-tactical missiles make their destruction possible at comparatively low altitudes and short distances

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

from the objectives being covered. The dimensions of the defensive zones of the fire weapons intended for the destruction of these weapons will be limited to several dozen kilometers.

As a result of this, groupings of these weapons may be used to cover individual objectives and compact groupings of objectives, mainly those located in border areas. It is completely possible that it will be feasible also to combat cruise missiles with complexes of this type.

The stability of an antimissile defense system will be determined, to a significant degree, by the stability of its radar system, for the disorganization of which the enemy will use both radio interference and strikes against its most important and vulnerable elements. In connection with this, a grouping of the PRO radiotechnical equipment must be created so as to ensure that the zones of radar detection are covered by the necessary number of sets. These elements of the system, like the centers of ultra-long-range detection, must without fail be screened by antiaircraft missile complexes.

The structure of the antimissile defense must be thoroughly coordinated with the grouping of the antiaircraft (protivosamoletnyy) defense weapons. In this case the stability of the antiair defense system as a whole is increased, and the enemy is deprived of the advantages that the joint employment of aviation and missiles could have given him.

Obviously, the deployment of the antimissile defense must be carried out in a definite sequence calculated so that it ensures covering, first of all, the most important areas and objectives, and at the same time so that conditions are created for the subsequent development of an antimissile defense, which includes new elements without reconstructing the system created earlier.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

It is known that the Americans plan to carry out the construction of their PRO system in two stages.

In the first stage such elements of the system are created as radar centers for ultra long-range detection and tracking of ballistic missiles, and fire weapons capable of covering comparatively small but the most important areas are deployed. Therefore, at this stage the system of fire cover may be considered to be a point system, receiving the necessary information about the targets from the territorial detection system.

In the second stage the number of fire weapons increases; their capabilities increase, mainly with an increase in the antimissile missiles' operating range. With this, the transition from covering individual objectives and fairly small areas to the defense of a considerable portion of the country's territory is carried out.

In stating our opinions concerning PRO, we proceed from the fact that an antimissile system is not autonomous, because the antimissile and antiaircraft defense are united into a single system of antiair defense of the country. It is also apparent that control of antiaircraft and antimissile defense at the operational level should also be unified. The question of tactical PRO elements requires study.

Control of antimissile defense must, in our opinion, be organized so that coordination of the operations of its individual elements and groupings and the most effective utilization of the antimissile weapons are ensured. Its material base must be a network of mutually connected command points making widescale use of automation for studying and evaluating the situation, making decisions, and for directing the combat operations of the forces and weapons. Before the start of an enemy missile attack, it appears that control of the PRO weapons must consist, primarily,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

of maintaining them at the necessary degree of combat readiness, of organizing coordination among the groupings of the fire complexes and among the radar centers of ultra long-range detection, and of comprehensive materiel-technical support.

In the process of repelling enemy ballistic missile attacks the control of the PRO weapons must consist of allotting targets among the radar centers and fire complexes, target designation, controlling the operating conditions of the radar sets, ensuring coordination between contiguous groupings of fire complexes, regulating the expenditure of antimissile missiles, and of other things.

The time available for performing the tasks enumerated is extremely limited. In conformity with the PRO system being developed in the USA, it will consist of not more than 10 to 15 minutes from the moment the missile is detected until the moment that it strikes. The "Nike-Zeus" fire complex requires only 4 minutes.

The limited time and the need to take into consideration a large number of factors, when working out a decision, require a high degree of automation of the control processes by using a whole complex of electronic computers at the command posts of all levels. In this, as shown by calculations, the operating speed of the EVM (elektronno-vychislitelnaya mashina-electronic computer) must consist of several hundred thousand operations per second.

The high level of automation of PRO, however, will not, it appears, rule out the participation of combat crews at the command posts during the process of controlling antimissile weapons. Their functions will be to react to unexpected changes in the situation, to introduce additional information, to analyze the developing situation, to clarify the initial data used in the algorithms of the machine resolution of

IRONBARK

[redacted] 1.3(a)(4)

tasks, etc. The equipping of command posts must ensure, practically, immediate reflection of the developing situation and of the status of the antimissile defense weapons.

The control of the antimissile weapons must provide for the cooperation of antimissile defense with the antiaircraft defense. Its goal is to operate against the enemy in the most effective manner with coordinated efforts. The cooperation must provide for:

-- concentrating the efforts of the antimissile and antiaircraft weapons for the defense of important areas and objectives;

-- questions of screening the weapons of antimissile defense;

-- coordinated use of radar reconnaissance means for discovering the start and the makeup of an air-missile attack, etc.

Thus, the main features of antimissile defense control will be: a high degree of centralization and subordination to a single command, comprehensive automation at all levels and echelons of command with the widescale employment of fast-operating EVM, and coordination of the operations of antimissile and antiaircraft weapons in the overall system of antiair defense.

Antimissile defense requires a reliable and fast system for transmitting information. Therefore, when organizing PRO, questions of communications, both from the standpoint of necessary technical means and from the standpoint of its organization, acquire an especially important meaning.

The exchange of information among the individual elements of the antimissile defense can be ensured only on the basis of the comprehensive employment

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

of various means of communication, even the use of special earth satellites. In the PRO system of the USA, for example, it is planned to use as communication links, cable lines, microwave band radio-relay links, and tropospheric communication radio lines, in which, the transmission of information to certain levels must be duplicated on different frequencies.

* *

*

In connection with the creation of an antimissile defense, a series of particular problems arises. Let us examine some of them.

In antimissile defense, timeliness in the detection of enemy missiles being launched acquires tremendous importance. In the example of the PRO of the USA, it is seen that such a system of early warning may be constructed on the basis of employing radar sets of ultra long-range detection, moved out to the probable axes of missile approach. However, this solution does not exhaust the problems. A more complete resolution of it is connected with the creation and employment of qualitatively new means - radar sets based on the principle of back-scatter probing (vozvratno-naklonnoye zondirovaniye) of the ionosphere, or artificial earth satellites with equipment that permits fixing the moment of launch of a ballistic missile.

Calculation shows that when such warning means are set up, intercontinental ballistic missiles may be detected about 30 minutes before they strike and intermediate-range missiles 10 to 15 minutes before they strike.

Plans for organizing early warning based on the use of artificial earth satellites are being worked out.

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

For example, one of them envisages a system made up of 72 satellites orbiting in six polar orbits whose planes are successively displaced in relation to one another by 60°. Twelve satellites orbiting in each orbit are the "simple cell" of the reconnaissance system that permits the simultaneous surveying of a strip of the earth's surface a little more than 6,000 km wide.

In each satellite, weighing up to 6 tons, it is intended to have an acquisition radar set operating on an impulse mode, with a range of up to 1,600 km and a scanning sector of 35°.

In view of the great operating ranges of the radar equipment and the extremely high requirements for accuracy of the radar information, important significance is acquired by the problem of studying the influence of the ionosphere on the errors of radar measurement of coordinates of high-flying objects and of working out methods to compensate for them.

It is known that when passing through the ionosphere a distortion of the path of radiowave propagation occurs and the speed of their movement changes. The first circumstance is the reason why errors occur in measuring angular coordinates, the second is the reason for errors in measuring distances. Moreover, the size of the error depends on the condition of the ionosphere.

Under the influence of factors originating in the cosmos, first of all radiation from the sun, the condition of the ionosphere constantly changes. These phenomena are both regular and accidental in nature. This leads to corresponding changes of the errors in radar measurements. Besides, within the ionosphere itself, there are dissimilarities of various scales, nature, the regularity of their appearance, the existence of which has not yet been studied

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

to the necessary degree.

The accidental nature of ionospheric phenomena makes it impossible to take them into consideration and to compensate for errors in radar measurements without knowing the laws that are inherent to ionospheric phenomena and without taking into consideration the current condition of the ionosphere and the forecast.

Especially important significance is attained by this question in view of the fact that nuclear bursts can bring about artificial ionization of the upper layers of the atmosphere and changes in the condition of the ionosphere enveloping the entire globe.

The problem of excluding mutual radio interference also takes on great significance. The powerful radiation of the radiotechnical equipment of the antimissile defense, if appropriate measures are not taken, will create powerful radio interference for the other radiotechnical equipment. On the other hand, the highly sensitive receiving equipment of the antimissile weapons may find itself subjected to a powerful influence from various radio transmitting and television devices.

In view of the use in antimissile defense of radar sets with a great pulse power the problem of biological protection of personnel has arisen.

The powerful radio frequency, and in some cases even roentgen radiation, that exist when operating radio equipment, are of danger to the health of personnel. Therefore the question of reliable biological protection requires most thorough study and elaboration of both technical means and organizational measures to ensure personnel safety.

It is apparent that the search for rational resolution of these questions must be along the line of employing a system of shield protection, and

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

IRONBARK

[redacted] 1.3(a)(4)

also a systematic measurement of the level of radiation in working areas, with automatic signaling when levels of radiation arise that are harmful to health.

* *

*

The powerful economy of our country and the great achievements of Soviet science are the materiel base that ensures continuous growth of the strength of the antiair defense of the Soviet Union. At the present time the antiair defense troops of the country are carrying out a new qualitative leap in their development.

Speaking at the XXII Congress of the CPSU, Minister of Defense Marshal of the Soviet Union Comrade R. Ya. Malinovskiy said: "I particularly have to report that the problem of destroying missiles in flight has been successfully resolved." This means that antimissile defense, for the antiair defense troops of the country, has already become a task of practical application.

The Role of Aviation in Military Operations at Sea

by

Rear-Admiral V. Bogolepov

The gigantic development of missile weapons compels one to ask the question: Will the missile in its triumphal advance diminish the role which manned aircraft have played up to now in military operations at sea? One must answer quite categorically: Not only will it not diminish, but rather, on the contrary, giving aviation more perfected weapons will even increase this role in the foreseeable conditions of warfare. To demonstrate this is the aim of this article.[1]

Two dual, basic strategic missions have always stood and still stand before the navy: operations on sea (ocean) communication lines, and operations in connection with the coast; in each case combat is conducted against enemy objectives and for protection of one's own installations.

Previously, which is very important, to these basic strategic missions was added, so to speak, an operational mission - the battle for supremacy at sea, which facilitated the accomplishment of both primary missions. As a practical matter, it also developed into a strategic, and in many cases, even into the foremost of strategic missions, inasmuch as its more or less successful execution (by destroying or blockading the enemy's fleet) automatically led to a suitable level of accomplishment of the basic missions.

At the present time, this battle for supremacy at sea has changed its meaning and character to a significant extent. First, under conditions of the diversity and the dispersion of naval power (including here, above all, aviation), it is almost impossible to neutralize or blockade the forces of the enemy so as to completely curb his activity; submarines and aircraft, especially pilotless, have broken "the law of numbers", so that within known limits they can operate even where the enemy has superiority of forces. Second, for the accomplishment of some missions, such preliminary neutralizing or blockading of the enemy's forces is not required. Third, modern combat against the main forces of the enemy - aircraft carriers or

1 While the present article deals with the question in an operational-strategic context and perspective, in the Collection of Articles (Sbornik statey) No. 4 of the "Naval Collection" (Morskoy Sbornik) Journal for 1960, in the article of P.P. Nevzorov, the same question is examined from operational-tactical positions.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

missile submarines - has as its goal, primarily, not indirect, but direct and immediate protection of one's own installations from their influence, and not only the naval but, primarily, land installations.

Undoubtedly, operations against enemy sea (ocean) communication lines and against shore installations in a number of cases already can be executed not only by naval and air forces, but also by land-based (nazemnoye) missiles. To be precise, sea (ocean) communication lines of themselves also include, along with those at sea, shore installations such as ports, hydrotechnical facilities, etc. But while earlier, because of the limited capabilities of naval weapons, the basic objectives on sea (ocean) communication lines were vessels at sea, now such basic objectives are frequently becoming those on shore.

Therefore, the question is what is more "profitable": to destroy all these objectives with land-based missiles or those from "intervening" (promezhtochnyy) missile carriers - submarine, surface, or air? Even elementary calculations show that a uniform solution to this question in all cases is impossible: Under varied conditions it is advantageous to use varied forces and weapons.

If one has in mind the probable enemy's stationary ground installations which are separated from us by water and whose precise locations we know, it would seem in all cases more advantageous to destroy them with land-based missiles, for this saves us not only from losses of missile carriers, but also from the necessity for creating these carriers.

However, in a number of cases, depending on the distances, on the nature of the antiaircraft and antimissile defense of the enemy, and on other elements of the situation, the use of "intervening" carriers may be fully warranted, partly because of the feasibility of simplifying construction and decreasing the size, weight, and hence, the cost of the missiles, partly because of their great accuracy of hit at lesser distances from the target, partly because mobile "intervening" carriers are less vulnerable to the enemy's missiles than fixed land-based launching installations, partly because these carriers may be needed anyway for performing other missions, and finally, as a result of the necessity for the enemy to expend weapons in these cases to combat the missiles and their carriers.

If one takes as a unit the military-economic cost of destroying in the initial period of a war not less than 15 to 20 percent of an

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

enemy industrial area measuring 60 by 20 kilometers by intercontinental ballistic missiles with nuclear warheads, then with regard to all the conditions enumerated, as well as the probable losses, the cost of accomplishing this mission by atomic submarines will be approximately the same, by diesel submarines-twice as much, by cruise missiles from land bases - three times as much, and by aircraft - several times more expensive. The expenditures of the enemy to counteract these strikes will be: for operations against missiles - 6 or 7 corresponding units, against aircraft - about 15, and against submarines - 20 to 30 units.[1]

Undoubtedly, these calculations, in view of their extraordinary importance, must be verified repeatedly and be defined more precisely for the most diverse conditions, for, depending on the situation, it will be advantageous to use one or another method of delivering missiles to the target.

If one speaks of "intervening" carriers, then it is very clear that it will be more expedient to use aircraft in case of relative weakness of the antiaircraft defense (PVO), and to use submarines in case of relative weakness of the enemy's antisubmarine defense (PLO).

Thus, one may conclude that in operations against enemy shore installations the role of aviation under modern conditions is rather modest, although in some cases it is not ruled out. It is more advantageous to use land-based and submarine missiles against such installations.

Let us proceed to an examination of methods of operation against mobile sea (ocean) objectives: the transportation means of the enemy, as well as his combat large units (soyedineniye) and vessels. The picture here is drastically changed.

The level of development of missile technology theoretically even now permits the destruction of any objective in any area of the world ocean by land-based cruise missiles, and in certain cases even by ballistic missiles. And, if one speaks of offshore (pribrezhnaya vodnaya) zones saturated with technical shore surveillance means, then such a solution to the problem, at least in relation to surface objectives, as a practical matter, is not only feasible, but in many cases even more advantageous.

---

1 An exposition of the methodology of these calculations requires a separate place.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In which cases? In those where the extent of the development of a theater facilitates the creation of the necessary system of missile launchers and shore installations in general. If this does not exist, then it is evident that it is simpler to utilize, for these targets, mobile forces and weapons, primarily aircraft. This question must also be solved on the basis of military-economic calculations based on initial operational-tactical requirements.

The width of the coastal zone now consists of several hundred kilometers and, in accordance with the development of technology, is growing continually. Extensive investigation must define precisely the order of this growth in the near future, but in any case one must consider that in some offshore naval theaters land-based missiles already are becoming the backbone of naval forces.

It may be asked: Why are land-based missiles regarded as a naval force, even if only provisionally? For the same reasons that "one gun on shore is worth ten guns on a vessel", as has been correctly assumed up to now, considering that one of the basic elements of naval forces is the so-called shore defense, including, above all, artillery. A naval direction is not necessarily connected only with vessels; it is connected with those forces and weapons by means of which it is more advantageous to accomplish the existing missions.

Concerning combat with submarines, in this zone the solution to the question depends on the method selected by us for detecting them. If this mission is assigned to fixed means (which at present can work only on the basis of hydroacoustics) having good communications with the shore, then detected submarines could be destroyed from the shore under conditions in which this will not disrupt the system of detection. But if the search and location of submarines is done by mobile forces, then these, naturally, will have the mission of destruction. As is known, the leading place among these forces belongs to aircraft, including helicopters.

Thus, the nature and degree of importance of one or another mission of aircraft in our offshore zone depends on the situation. But if the basic weapon against enemy surface forces in some cases is land-based missiles, then in combat against his submarines a prominent place, along with small vessels, as before, belongs to aircraft, in particular helicopters.

It must be added that if the operational range of shore missile

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

weapons is superior to the range of shore technical means of surveillance and target designation, then in this "external" part of the offshore zone the significance of aviation will grow still more as a result of the assignment to it of the mission of surveillance (reconnaissance), target designation, and, when needed, guidance.

We shall turn to an appraisal of possible methods of operations against mobile enemy objectives located outside the offshore zone just examined. If one speaks of enemy submarines, then, naturally, detection and destruction of them outside the offshore zone by some type of fixed or shore means is impracticable, and may be accomplished only by surface and air forces. If one speaks of surface ocean objectives, then elementary calculations show that the destruction of them from the land, although possible, demands such cumbersome missiles and such a complicated system of target designation and guidance that in an overwhelming majority of cases it is much more profitable to destroy them with missiles from mobile, specifically "intervening", carriers. Which carriers in this realm are most advantageous - submarine, surface, or air?

As is known, we have set aside surface ocean forces as a result of a number of considerations. Therefore, the discussion may proceed solely with submarine or air forces.

Unfortunately, the requisite comprehensive examination of this question does not yet exist. Preliminary calculations permit one to assert that the most advantageous carrier of weapons at sea is indeed aviation.

The experience of history confirms this concept. Thus, while in the First World War, aviation, especially at sea, only spread its wings, in the Second World War, its share was already from one-third to one-half of the destroyed and damaged combat vessels and ships of all combatant nations. As long as manned aviation is compared here, not with missiles (for it itself uses missiles), but with the other "intervening" carriers - surface and submarine, then there is no doubt that this process of the increasing role of aviation in operations in open sea (ocean) theaters will continue. In addition, without the assistance of aviation, the operations of submarines, especially diesel, are made much more difficult.

Concerning intelligence, as is known, even with the comparatively favorable ratio of the rates of speed of German submarines on the surface and merchant ships in the First and Second World Wars (respectively

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

10 to 15 knots for the submarines and 6 to 10 knots for the transports), the effectiveness of the submarines' combat operations depended to an extraordinary degree on their receipt of timely and precise data on the movement of convoys and ships. Now the ratio of these speeds is becoming all the more unfavorable for diesel submarines (15 to 18 knots for them and 10 to 16 knots for the transports). But in addition, while submarines traveled on the surface in the past war, especially at night, comparatively without hindrance, and were able to overtake and repeatedly attack convoys, now, with the widespread participation of aviation in antisubmarine defense, this is almost ruled out. The underwater speed of diesel submarines with regular use of the RDP (submerged diesel operation-rabota dizelya pod vodoy) apparatus does not exceed an average of 4 or 5 knots.

As a result, when the enemy has at his disposition routes in an ocean zone with a width of 500 to 600 miles, then for dependable assurance of only a single attack of a convoy by a group of submarines, it is necessary to deploy ahead of this group two reconnaissance screens of 15 to 20 submarines each. With a coefficient of operational utilization[1] of diesel submarines of not more than 0.1 to 0.15 for such uninterrupted reconnaissance (and only for reconnaissance), it would be necessary to have for only one ocean direction, not considering possible losses, 200 to 400, or as an average, about 300 submarines, at a total cost of 12 to 15 billion rubles. Meanwhile, for the accomplishment of the same reconnaissance mission by aviation, with two or three flights daily by paired flights of aircraft and with an intensity of 6 to 8 flights per month for one aircraft, 16 to 30 are needed, or an average of 20 to 25 aircraft with a total cost of 1 to 1.5 billion rubles. Figures are eloquent, and with regard to possible losses, such a comparison will be still more to the disadvantage of diesel submarines.

Of course, the mission of reconnaissance now can also be accomplished by pilotless means. If one bears in mind the long-term possibilities in this connection of artificial earth satellites (ISZ), which could systematically give a complete picture of movement on the oceans, then the conclusion follows that the speedy realization of that prospect should be worked at persistently. But if the discussion concerns the so-called reconnaissance missiles, then they, especially from submarines, may be launched only for

1 By coefficient of operational utilization is understood the relation of the time of the submarine's stay in the area of combat operations (i.e., without taking into account the time/remainder of footnote missing/.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

tactical elaboration of an already known operational situation, and to effect reconnaissance of the latter is actually much simpler and more convenient with the aid of manned aircraft.

Perhaps these calculations and conclusions will appear to someone to be exaggerated. But, it is enough to analyze the experience of the Second World War, in particular the extraordinary decrease in the effectiveness of the operations of German submarines because of their poor aerial reconnaissance support, in order to arrive at the same conclusions. And since at present the main bulk of submarines still have diesel-electric engines, the question of supporting submarines with aerial reconnaissance is exceptionally important.

Of course, nuclear submarines present another perspective. Considerably surpassing in their submerged speed the average speed of convoys, they can combine reconnaissance with attacks, even repeated attacks. Calculations still show that aerial reconnaissance can also substantially increase their effectiveness.

The close combat assistance of aviation is no less important for diesel submarines. Being obliged regularly to proceed under RDP from one fourth to one third of the time, for recharging their batteries, even though not rising to the surface, diesel submarines all the same are comparatively easy to detect by the radiotechnical means of the enemy's aviation. Hence, for a more or less reliable guarantee of their security, regular combat against enemy aviation is necessary - a mission which, on the ocean again, can be accomplished only by a sufficiently long-range (avtonomnaya) and powerful combat aviation.

There is no doubt that operational and combat coordination with aviation is also advantageous for nuclear submarines. Thus, the role of aviation in combat against mobile objectives of the enemy on the ocean, i.e., against his combat forces, primarily aircraft carriers, and against his convoys and transports, has even increased; moreover, not only directly in relation to combat, but also in the realm of supporting operations of submarines, especially diesel submarines. It may be asserted that now a greater role in operations at sea in general belongs to aviation.

Up to this point the discussion has concerned itself with the possible participation of aviation in the fulfilment of the first, "offensive", half of both basic missions of naval forces - operations

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

against the shore and against ocean objectives of the enemy. At the same time, a second, "defensive", half of the first mission has appeared for examination, i.e., the defense of one's own shore installations, since operations against enemy aircraft carriers and submarines are really the execution of this mission.

What is the possible role of aviation in fulfilling the second half of the second mission, i.e., in the defense of one's own communication lines? If one speaks of the very real, for us, securing of them in the immediate offshore zone (with a depth in modern conditions, as has already been noted, of several hundred kilometers), then depending on the situation, land-based missiles and aviation must serve as the basic means of defense of communication lines from surface forces of the enemy.

Our small vessels of the patrol boat (storozhevoy kater) class ("subchasers" - okhotnik), together with aviation can fully protect shore communication lines from the submarines and air forces (VVS) of the enemy. It should be noted that in spite of some views the possibilities for aerial combat will in no way be curtailed. The history of the development of weapons irrefutably proves that when the conduct of combat by conventional means between any types of newly appearing major elements of armed forces (weapons carriers) becomes impossible, then human ingenuity finds a way out of the situation by creating new combat means. Thus it is here. While the tremendous speeds and great turning radii of modern airplanes prevent visual observation of the enemy and the utilization of cannon-machine gun armament against him, technical means of surveillance are arriving to assist the eye, missiles are appearing in place of machine guns and cannons, and the work of the brain is made easier by electronic computers.

Of course PVO vessels carrying a number of antiaircraft missiles, as well as helicopter vessels of the PLO, could also be useful for these purposes. However, the role of the PVO vessels will be too passive: owing to the short range of operation of their weapons, they cannot combat the enemy's aviation itself, but only the missiles launched by it. Concerning helicopter vessels, for each specific direction, one must consider whether it is not more advantageous to have landing areas for the helicopters on shore in place of the helicopter vessels.

There is no doubt, finally, that the transports themselves can be equipped with antiaircraft missile launchers and that they also

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

can carry helicopters.

Thus, for the defense of close communication lines, shore-based aviation, including helicopters, have, as before, vital importance. What is its possible role in securing distant ocean communication lines? It must be said directly, that with its present range, aviation is not in a position to defend ocean communication lines, and that the defense of them now is feasible only for aircraft carrier aviation. This is precisely why the USA continues to build aircraft carriers - vessels which in their time were actually born from the insufficient range of aviation: our enemy cannot manage without ocean communications, and without aircraft carriers these communications are indefensible.

Of course, aircraft with a long flight range could, being based on the shore or near the shore, cover ocean convoys or large units of surface vessels "in watches" ("povakhtenno"), taking off from the shore and returning there. But the cost of such coverage will turn out to be less than the cost of aircraft carrier support only when the shore-based aircraft gain not less than several days' range.

This is why, while continuing in the meantime to construct aircraft carriers, the Americans at the same time have been working strenuously in recent years on the creation of a nuclear power plant for aircraft. There is no doubt that we have every possibility of outdistancing the USA in this connection.

But if sufficiently long-range (avtonomnyy) and cargo-carrying aircraft are created, then perhaps with their assistance transoceanic transport can be realized, at any rate, military.

To this, one may answer that cargo merchant marine transport will be retained in the foreseeable future owing to its great economy in comparison with air transport, and on the strength of the fact that along with regularly scheduled, there will always be irregular transport (seasonal, etc). In connection with passengers, the situation is different: even now, more and more people prefer air travel to travel by sea. In wartime the situation changes still more. During the Korean War, 1950-1953, the Americans transported by air about 5 million persons (true, in the same time, about 80 million persons by sea) and about 0.08 percent of all cargo. But the application of nuclear power to aviation will undoubtedly open here completely new perspectives in the area of the freight-carrying capacity of individual aircraft and in relation to the overall freight-carrying capacity of aviation.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Will the cumbersome shipment of troops by sea transport still remain? It is doubtful. But the role of aviation in military operations at sea will become even more important.

We shall summarize our arguments by means of a small table.

The Role of Shore-Based Aviation in Military Operations at Sea			
Missions of Naval Forces			The Role of Aviation in Modern Conditions and in the Future
Operations in relation to shore installations	Against installations of the enemy		Manned aviation yields its role to pilotless aviation, but in some cases may be utilized.
	Protection of one's own installations		In combat against combat forces of the enemy-mainly against aircraft carriers, missile carriers, and to a certain extent also submarines-the first place belongs to manned aviation.
	Against communication lines of the enemy		Against shore installations of communication lines (see above); in operations against sea (ocean) objectives of communication lines, manned aviation plays a direct and essential role, and also in support of submarine operations.
Operations on communication lines	Protection of one's own communication lines	Close	Plays a large role
		Distant	At the present time it cannot protect distant communication lines. In the future it will protect sea transport and will also carry it out directly.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Thus, at sea the relative weight of shore-based aviation not only remains high (with the assimilation of missile weapons by aviation), but in the future it will increase still more.

What kinds of aircraft are needed for operations in sea (ocean) theaters?

First and foremost, if this is not prevented by other circumstances, seaplanes, in particular, flying boats (lodka), are most advantageous, not only with regard to their ease of basing (both on a strip of water near the shore and deep inside the country), but also because, in a number of cases, by landing on water in the course of accomplishing their mission they may increase their range. It is really unnecessary to speak in this regard about aircraft specially designated for coordinated operation with submarines, for conveying supplies to them, or, on the other hand, for receiving supplies, in particular, fuel, from submarines.

Other demands on naval aviation must be outlined mainly depending on the planned area of its operations. In regard to aviation for coastal waters, it can manage without special range, although for some classes of aircraft, for example, reconnaissance aircraft, antisubmarine, and PVO aircraft guarding convoys, greater range would be useful. To the extent that this is "our zone" and we must always have air superiority here, especially high speed for these aircraft is not required, the main need is for excellent means of surveillance (including detection of submarines) and weapons.

On the other hand, especially great range and maximum speed (now not less than 1800 to 2000 kilometers per hour) in order to have the capability of evading an air enemy with superior forces are required for ocean-going aircraft. It should not be said that the best way to fulfil both demands will be secured by a transfer to nuclear power, the introduction of which to aviation, however, should be given most serious attention.

In the first volume of the secret military-historical essay The Navy of the Soviet Union in the Great Fatherland War 1941-1945, it is justly said that the main striking force of the Navy in World War II was aviation. Despite the systematic utilization of naval aviation for operations on ground axes, owing to the situation which arose, it still occupied the first place in inflicting losses on the enemy at sea. At the same time, it is noted in this work that by

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

the beginning of the war "qualitatively, our aviation...in the navy was significantly inferior to the aviation of the enemy..." (page 76). Only 12.5 percent of the aircraft were new types; the remaining types were obsolete. "The lag of aircraft in a technical sense, principally in speed, and also their numerical deficiency in each of the operating fleets, created significantly difficulties in the initial period of the war" (page 62). Everyone knows what urgent and most energetic measures were required in order to correct this situation. And even long before the war, a basis already existed for considering that aviation in the near future would occupy the place of the basic striking force in combat operations at sea and, in addition, in the Basic Considerations in the Development of the Navy (VMS) of the Workers' and Peasants' Red Army (RKKA) during the Second Five-Year Plan it was indicated that "The most important and decisive role must belong to submarines and heavy aircraft" (page 46).

Such are some conclusions, not so much from a theoretical, as from a practical, underestimation by us of the significance of aviation in operations at sea before the last war. There is no doubt whatever that on the basis of attentive study of the experience of the last war, exhaustive analysis of the new requirements of the situation, the powerful development of Soviet science and technology, and, finally, the gigantic potential of our industry, we shall not repeat the old mistake.

Of course, in a journal article one may take up the question being examined only on a very general plane. But its importance urgently demands the most attentive and detailed examination of both the question as a whole, and of all its individual facets.

DATE OF INFO: October 1960

APPRAISAL OF CONTENT : Documentary

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Air Forces in the New Stage of Development of the Soviet Armed Forces", written by Lt.-Gen. of Aviation S. Sinyakov and Maj.-Gen. of Aviation M. Kozhevnikov.

This article appeared in the 1960 Third Issue of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET by the Soviets and is issued irregularly. It is distributed within the Ministry of Defense down to the level of Army Commander. The 1960 Third Issue was sent for typesetting on 17 October 1960.

Headquarters Comment: The article referred to on page 5 was disseminated as [redacted] 1.3(a)(4)

The Air Forces in the New Stage of Development of the Soviet Armed Forces

by

Lt.-Gen. of Aviation S. Sinyakov

and

Maj.-Gen. of Aviation M. Kozhevnikov

The well-known postulate of F. Engels on the direct dependence of the armament, composition, and organization of troops, and their tactics and strategy, on the degree of development of industry, finds brilliant confirmation in our Soviet reality. The uninterrupted and stormy growth of socialist economics and the realization of technological progress in all branches of the peoples' economy, especially in heavy industry, has made it possible to supply the Soviet Army with the new nuclear/missile weapon, which has radically changed the quality of all the types of our armed forces, including the air forces (VVS).

The introduction of the nuclear/missile weapon was accompanied by a process of formation of new opinions regarding the preparation for and conduct of modern operations and of war as a whole. The nuclear weapon has changed the role and place of every type of armed forces and arm of troops in armed combat, in an operation and a battle, by advancing to first place a new, more powerful type of armed forces - the missile troops - to whom belongs the basic role of disorganizing the enemy rear, his economy, and system of governmental control, and also, of destroying the enemy's long-range means of attack.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

At the same time, it is quite obvious that no single type of armed forces is in a position, if isolated from the other types of forces, to perform successfully the combat missions assigned to it. The achievement of victory in a future war will be possible only with the united efforts of all types of armed forces and with their coordinated operations on land, in the air, and on water. The interdependence of all types of armed forces and arms of troops will increase significantly in a future war, since, with the employment of missiles and aircraft, war will reach all corners of the globe, the distance between the rear and front will disappear in fact and the losses in military equipment and personnel will increase many fold as compared with the last war. Continual mutual assistance and cooperation will be required between all types of armed forces in fulfilment of combat tasks, as well as in materiel-technical and medical support.

The air forces, owing to the availability in their composition of various types and kinds of aircraft, are capable of fulfilling diverse combat tasks, and because of their high mobility they are very closely bound to all types of armed forces in combat operations.

In fact, missile troops equipped exclusively with powerful combat means can at any time of the day and irrespective of weather conditions penetrate the air space of the enemy relatively freely and strike all of his stationary and low-mobility targets on land and water. But these troops urgently need to have aerial reconnaissance information on the targets of operations and on the results of their strikes.

The ground troops, despite their increased fire-power and penetrating ability, require the assistance of other types of armed forces, particularly aviation. The VVS, jointly with missile troops, can successfully strike the approaching enemy reserves and disrupt his communications. Military aviation participates directly in the combat and in the operations of ground troops by supporting and covering them in cooperation with other

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

arms of troops. For the ground troops and for all other types of armed forces, reconnaissance aviation is and will be for the immediate future the only means of ensuring the receipt of reliable information on the activities and intentions of the enemy in the depth of his rear and on all close approaches to the front, just as military transport aviation is and will be the most mobile means of transporting troops and cargo.

The troops of PVO of the Country are interested in the neutralization and destruction of enemy means of aerial attack, especially of his missiles of all systems while still at their places of concentration and at their bases. It is quite obvious that only missiles and aircraft can neutralize and destroy enemy means of aerial attack at the locations of their concentration and bases. Fighter aviation and guided antiaircraft missiles of fronts, by delivering strikes against an aerial enemy in flight into the depth of the country, cooperate significantly with the troops of the PVO of the Country in the fulfilment of the important task assigned to them of covering the territory of the country from air strikes.

The navy, using submarines and missile-carrying surface vessels, can operate successfully against the enemy's ocean and sea communications only in close cooperation with reconnaissance and missile-carrying aviation. Effective combat with enemy aircraft carriers and missile-carrying vessels, just as with constantly maneuvering objectives, is possible in modern conditions only by aircraft armed with missiles of the "air-to-vessel" class.

It is quite likely that the enemy fleet, having received the signal of combat alert during the threatening period, will leave its stationary bases and will proceed to the vast sea and ocean spaces. Because of this, it will be practically impossible to catch military vessels at their bases through the launching of the first strike with the "surface-to-surface" (zemlya-zemlya) class of missiles. From

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

this it becomes quite clear that destruction of enemy aircraft carriers and missile-carrying vessels will have to be carried out by the forces and weapons of missile-carrying aviation and submarines.

Consequently, the air forces as a type of armed forces must be separate and complete, because in a future war they will have to perform tasks in cooperation not only with one type of armed forces but concurrently with all of them. Therefore it is impossible to agree with the opinion of Colonel-General A. Gastilovich, regarding the expediency of transferring the long-range aviation to the navy, which was expressed in the article "The Theory of Military Art Needs Review".[1]

In examining the problems of combat use of our VVS; and also in determining its role and place in modern operations and in warfare as a whole, it is advisable to proceed from the need to secure close cooperation between all types of armed forces, without which it is impossible to achieve success in modern armed combat.

It is known that the air forces, owing to the transfer of a number of their combat missions to the missile troops, have lost their monopolistic position in the destruction of many enemy objectives, especially those located on other continents. In this connection, the VVS sphere of operations in the intercontinental field has narrowed, but in theaters of military operations and in front troop operations it has significantly widened.

In the present article it will be advisable to examine certain already partially determined trends and directions in the combat use of the various types of aviation in modern operations. It is necessary to do this because the appearance of missile troops has generated many varied interpretations of combat use of aviation in modern operations and in warfare as a whole.

1. Special Collection of Articles of the Journal "Military Thought", First Edition, 1960, page 6.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In order to understand more correctly the peculiarities of combat use of VVS under the new conditions, we will begin with an examination of the qualitative changes which have occurred recently in aviation and of the combat characteristics of VVS, which derive from the nature of the various types and arms of aviation.

In the air forces, as in the other types of armed forces, the nuclear/missile weapon is becoming the basic type of weapon of strategic, long-range, and front bombers and is gradually being assimilated by fighter-bombers and fighter-interceptors. Data on the quantity and combat capabilities of aircraft - the carriers of nuclear bombs and missiles of the "air-to-surface" and "air-to-air" classes - are the basis for all calculations in answering the question of the combat complement and the structure of combat formations of aircraft, getting them to the targets of operations, evaluating VVS combat capabilities, and organizing control of them. Missiles of the "air-to-surface" class, which can be launched from strategic aircraft located at a distance of up to 600 kms from the target, ensure the destruction of specific objectives from long distances without the need for aircraft to penetrate the enemy PVO zone. As a matter of fact, the mother aircraft (samolet-nositel) becomes a missile-carrying aircraft (samolet-raketonosets) and the commonly used term "bomber" will obviously disappear with time from our military lexicon and will be replaced with the term "missile-carrier". The appearance of the aircraft-missile carrier -- this is the most important qualitative change that has taken place in the VVS -- has permitted a reduction in the combat complement of aviation operational formations (obyedineniye) and large units (soyedineniye) and, at the same time, even more effective execution of combat tasks. The determining factor is no longer the quantity of airplanes carrying out a strike on a target, as it was in the recent past, but their quality; for example, their capability to carry nuclear weapons and, under conditions of a strong enemy PVO, to locate moving targets quickly and to destroy them.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

In fighter aviation the guided-missile weapon of the "air-to-air" class is acquiring increasing significance, and is becoming the main type of weapon of modern fighters. This weapon permits the destruction of aerial targets in all weather conditions at distances of 3 to 5 times greater than the fire range of existing modern aircraft cannon and ensures the interception and destruction of aerial targets on approaching courses and from the forward semicircle (s peredney polusfery). The guided-missile weapon and the supersonic fighter flight speed of 2,000-2,500 kms/hr ensure the destruction of enemy cruise missiles, aircraft, helicopters, and aerial balloons.

Military-transport aviation is being equipped with new heavy freight capacity and with faster aircraft and helicopters capable of transporting troops and freight not only within the limits of one front and one theater of military operations but also between different theaters of military operations.

In the very near future, major qualitative changes will occur in reconnaissance aviation. This process will acquire an ever larger scope by its being equipped with new manned and pilotless cruise reconnaissance vehicles (bespilotnyy krylatyy razvedchik), and also with night-vision apparatus and automatic transmission of reconnaissance information from the aircraft to the screens of the appropriate command posts.

The increased speed, flight altitude and other features of our aircraft as carriers of nuclear weapons, and also the improved capabilities of active and passive PVO means, are connected with the successful mastery of all types of jet engines (turboprop, turbojet, ramjet, rocket). In comparison with conventional aircraft, they possess much greater thrust with lighter weight, and they impart to an aircraft, whether with liquid or solid fuel, exceptionally great speed which has not as yet been fully exploited, and in addition they have unlimited altitude. The appearance of aircraft with atomic engines will ensure the possibility of flights of unlimited distance.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Electronics are far from being the least element influencing the basic qualitative changes in our VVS. Radioelectronic apparatus has made it possible to achieve more effective guidance of manned and pilotless means of attack and defense than was possible previously. In manned equipment, electronics has brought about the realization of complete or partial automation, without which the flight of aircraft (including bombers) would have been inconceivable with a crew at modern supersonic speeds. Radioelectronic apparatus permits control from the ground or from the mother aircraft of pilotless cruise missile flights.

The further development of aviation weapons will permit us, in the next few years, to have ballistic missiles of the "air-to-surface" class along with cruise missiles, within the armament inventory of supersonic strategic and long-range bombers.

At the present time the question of the need for creating rocket aircraft has become acute. In a future war, rocket aircraft, combining the combat characteristics of missiles and aircraft, and piloted by a human, will play a highly important role in space (kosmos) combat and in the destruction of the most important objectives on distant continents. The creation of rocket aircraft is a most immediate and completely practicable task in the development and construction of our air forces. There is no doubt that rocket aircraft, as an absolutely new and longer range weapon of the VVS, will find broad application in a future intercontinental war.

These are the qualitative changes taking place in our air forces and representative aspects of future development in military aviation.

Let us examine those combat characteristics of the VVS which are inherent to them alone and which retain their importance in the new phase of the development of the armed forces. Among these combat characteristics should be listed:

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

-the high mobility and capability of the VVS to perform rapid maneuver with piloted means on operational and strategic axes and in theaters of military operations;

-the capability of carrying out independent search for and preliminary reconnaissance of targets assigned for destruction and of annihilating them either when they are on the move or when stationary;

-the ability to retarget more rapidly than other means, while airborne, against new targets which suddenly appear or against targets whose locations have changed;

-the capability to observe the enemy's operations from the air, to discover his intentions, and to transmit the reconnaissance information immediately to the command posts of all types of armed forces;

-the capability to support an airborne troop landing and to provide rapid air transport for troops and freight for any distance.

Mobility to one degree or another is also characteristic of other types of armed forces, but in the VVS it is notable for the fact that military aviation is capable, by maneuvering rapidly with piloted combat equipment, to ensure its immediate entry into combat. This should be emphasized particularly because under conditions of great destruction of railroad and automobile communication lines, relatively speedy reinforcement of separate fronts and active theaters of military operations with forces and weapons from other axes will be possible only by combat aviation, if we do not consider implementation of maneuver by fire of ballistic missiles of operational-strategic designation. Within 2 to 5 hours after receiving the order and notification of combat alert, aviation large units and units of the VVS can (depending on the types of aircraft) take off and carry out the assigned combat task in the direction or in the theater of military operations indicated to

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

them. If, in this event, the aircraft are in a situation of "ground alert" (dezhurstvo na aerodrome) the time will be decreased to 15 to 25 minutes. It is absolutely clear that no other type of troops will be able in such a short time to maneuver even within a single theater of military operations.

A remarkable combat characteristic which only aviation possesses is the ability to combine independent search by aircraft crews for the assigned targets and the destruction of them by nuclear and conventional weapons.

In reality, we all recognize that a future war will have a highly maneuverable and destructive character. The troops, in order to escape enemy nuclear activity, will constantly strive to change location. The troops operating in the first strategic echelon will require more frequent reinforcement and the uninterrupted delivery of materiel means (ammunition, fuel, food) from the rear areas. All this, in the final analysis, will result in a stream of freight trains, numerous vehicle columns, and flights of transport aircraft and helicopters from the rear area to the front. If it were to be calculated, one could confirm the fact that a group of U.S. armies in the Western theater of military operations can have up to 45 percent of its installations mobile. It can be expected that during combat operations at least half of the enemy armed forces will be in a constantly mobile status. Combat against such mobile objectives can be carried out principally by aviation and partially by missile troops. In this event, missiles of the "surface-to-surface" class require the precise coordinates of each target, and with moving objectives, as is known, they change constantly. Therefore missiles can destroy mobile targets only on the basis of previously calculated coordinates, in narrow defiles, at road crossings, and also at loading and unloading places. All moving objectives can be most reliably destroyed, only by piloted aircraft, whose crews need only information as to the area in which moving enemy troops and equipment have been detected.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

The ability to see the enemy from the air and to observe his activities in both the deep and close areas of the rear -- this is a characteristic peculiar to aviation. It is difficult to overestimate it, if we consider that without reconnaissance information, which is obtained with the aid of aviation, it would be impossible to carry out modern operations.

As concerns airborne troop landings and the rapid transport of troops and freight for any distance, irrespective of the availability and condition of roads, aviation still remains the only means for performance of such tasks. The need for military-transport aircraft and helicopters is continually increasing in all types of armed forces, but under conditions of mass use of nuclear/missile weapons, aircraft and helicopters will in many instances be the only means to provide for the maneuverability of the troops and for timely materiel-technical supply to them.

On the basis of a brief analysis of the qualitative aspects and the combat characteristics of our VVS, it is possible to determine their combat tasks in warfare.

In the not too distant past, air forces, as is known, were responsible for three basic tasks:

-the disruption of the military-economic potential of the enemy;

-the struggle for supremacy in the air;

-cooperation with the ground troops and the navy in the successful conduct of operations.

In the past war all of these missions were successfully fulfilled by the Soviet air forces. This is especially apparent, for example, in the fulfilment of the second and third tasks by them.

As is known, in the middle of the summer of 1943 our aviation wrested the initiative from the hands of the enemy in heated combat and, after winning the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

battles for the Kuban and at Kursk, firmly secured supremacy in the air. By uninterrupted support and cover of the ground troops, our aviation actively cooperated in the destruction of the armed forces of Fascist Germany. The VVS activities against railroad networks, military-industrial targets, airfields, and groupings of troops, transformed aviation during the course of the war into a factor of strategic significance. Even after the war and right up to the appearance of missile troops , the VVS were actually the strategic means of combat and were the main striking force capable of subjecting the deep enemy rear to destructive nuclear action.

After the appearance of missiles of strategic and operational-tactical designation, the situation changed radically. Missiles, possessing the capability to reach any distant target strongly defended by enemy PVO means, will be able to fulfil the most important strategic missions. They will be used primarily along the main axes, where the most important large and stationary enemy objectives are located, well-screened by antiaircraft guided missiles. Despite this, one cannot overlook the fact that the enemy has many important mobile objectives, and that there are areas which are not screened by an effective PVO. Naturally, it is expedient to use long-range and strategic bombers in these directions.

Therefore, the first task - disruption and reduction of the military-economic potential of the enemy -which was previously the responsibility of the VVS, has now passed in significant degree to the missile forces. The very contents of this task have changed. It has assumed a more decisive character and consists now of the mass and rapid destruction and annihilation of the most important targets of the enemy's rear. In fulfilment of this broadened task, the air forces, in the new conditions, take an active part by concentrating their efforts on the destruction of targets mainly in directions not well covered by PVO means.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The second mission - the fight for air supremacy - as one of the most important missions previously assigned to the VVS, has lost its earlier significance due to the appearance of missile troops. But in its place there has appeared a new, even more complicated task - the struggle against enemy nuclear/missile means of attack, which, in its significance to warfare, acquires paramount importance. Its significance flows from the colossal increased destructive might of nuclear/missile weapons. In a future war a stubborn, bitter struggle will develop between the warring sides for nuclear superiority and for more effective exploitation and use of nuclear weapons for more rapid achievement of strategic goals. Both sides will vigorously seek to locate the antagonist's nuclear/missile weapons and to destroy them immediately. It can be confidently stated that whoever resolves this task faster will win the battle and, consequently, the war. For this, it is necessary to have in constant readiness, not only missile troops, but also military aircraft and means of aerial reconnaissance that are capable, at the start of the war, to survey all corners of the globe that are enveloped by war, and later to carry on constant observation of the enemy on land and water.

In this connection, the task of the struggle with the enemy's nuclear/missile means of attack becomes the primary one for our missile troops. The air forces will take a most active part in its fulfilment.

The third most important task of the VVS - cooperation with the ground troops and the navy in their operations - remains fully intact under the new conditions. Military aviation takes part in cover and support of troops from the air, in the battle with the enemy's means of nuclear/missile attack and his reserves, in support of airborne troop landings, and in air transport of troops and freight.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4

[redacted] 1.3(a)(4)

The fourth task of the VVS - combat against enemy transport operations via his ocean, sea, land, and air communication routes. Under the new conditions of waging war, this task will undoubtedly assume an operational-strategic scope.

The fifth task of the VVS - aerial reconnaissance. This VVS task is becoming, in its operational-strategic significance, no less important than all the other tasks. Therefore it seems expedient to us to raise aerial reconnaissance to the category of the independent and most important tasks of the air forces.

These are the combat tasks which must be fulfilled by the air forces in modern warfare with consideration for the existing capabilities of aircraft and the immediate prospects for receipt of new aircraft equipment into the armament. The many-sided nature of VVS tasks resulting from the new conditions also predetermines the need for long-range, front, and military-transport aviation within its composition.

Let's examine the apparent and already partially determined new trends and directions in the combat use of various types and kinds of aviation under conditions of wide use of missile weapons in the conduct of operations by the ground troops in the initial period of a war.

The experience of a number of aviation exercises carried out jointly with the troops of PVO of the Country indicates that the VVS's first massive strike against the enemy in the beginning of a war can be executed immediately following the first missile salvo, but that aerial reconnaissance must start fulfilling its assigned tasks simultaneously with the initiation of the first launch of missiles. The subsequent activities of long-range and strategic bombers, and cruise missiles with nuclear warheads, will similarly be carried on between the missile salvoes (strikes). Such a sequence of operations of the missile troops and of the VVS creates for the VVS two quite new situations, one of a positive, the second of a negative, nature.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Missile troops, simultaneously with the destruction of assigned enemy targets by nuclear warheads, inevitably destroy and annihilate the forces and weapons of his antiaircraft defense and thereby disrupt the only control system for enemy antiaircraft missiles and fighter-interceptors. This assists the long-range and strategic bombers to overcome enemy PVO.

But in this connection, during the course of a missile strike, the necessity arises to transit air space heavily contaminated with radioactive fallout. Therefore, the probability of air-crews entering a zone of radioactive contamination significantly increases at night and with adverse weather conditions, during daylight, when visual determination of the limits of the radioactive cloud is almost impossible.

These two circumstances strongly emphasize the need for continuous coordination between the respective headquarters of the missile troops and of the air forces. It must be expressed primarily in the assignment of targets of the operations, in the assignment of a time schedule for the missile strike and for mother aircraft, and in the determination of altitudes for the burst of nuclear charges. In practice it is possible to coordinate missile and aviation operations against enemy targets in the same area if they are plotted on a single board which reflects the combat capabilities of the missiles and aircraft being used.

For the air forces, even under the new conditions, the basic method of operations in the initial period of a war will be the execution of powerful massive strikes, with subsequent transition to operations by small groups on a broad front following the missile strikes.

The form of operational employment of the VVS under conditions of the initial period of a war remains the air operation, i.e., massive strikes with its entire strength. In its content, the air operation will have a somewhat different nature than previously. In the first place, it will be carried out under conditions

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

of wide use of missiles; because of this, its duration will be sharply reduced and the immediate task can be fulfilled by the initial massive strikes, as the experience of training exercises indicates. In the second place, the air operation will be carried out by the entire or the major portion of the forces of long-range aviation, with the participation of front aviation. In such an operation the decision regarding the fulfilment of assigned tasks will ordinarily be made by the Commander-in-Chief of the VVS. In the third place, the targets and areas of operations of the VVS in an air operation will be determined by a higher command, depending upon the operations of the missile troops.

One of the main conditions for fulfilment of tasks by long-range and strategic bombers, as regards the destruction of targets in the enemy rear areas, is their successful overcoming of enemy PVO means. Wide use of low flight altitudes by bombers, and the use of passive and active jamming (pomekh), are highly effective. It was determined during training exercises that the percentage of aircraft attacked by enemy fighters in daylight at high altitudes was 5 or 6 times greater than at lower altitudes and at night it was quite insignificant. Destruction of aircraft by guided antiaircraft missiles during low altitude flights is limited by the combat characteristics of the anti-aircraft missiles. Thus, absolutely clear-cut determination was made of the direction of the use of existing long-range and strategic bombers against targets located in theaters of military operations - at night and at low altitudes. Low altitudes are becoming the basic operational altitudes for long-range and front aviation.

The training exercises carried out this year confirm the assumption that during the execution of the first retaliatory strike, a single echelon operational formation of long-range aviation forces and the overcoming of the pre-frontal zone on a broad front are the basic form of operational maneuver.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

These are some of the new tendencies and trends in the combat use of the VVS in conditions of the wide utilization of missile troops during the initial period of a war.

Let us examine definite directions in air operations when fulfilling tasks in cooperation with the ground troops in their operations.

It is known, that of all the types of aviation, front aviation plays the main role in the operations of the ground troops; during the recent past it has undergone major qualitative and quantitative changes which have resulted in a significant impact on the nature of the tasks performed by front aviation. For example, with the appearance of nuclear weapons, the main content of the air struggle with the enemy's means of attack changed from the destruction of enemy aircraft in general to the destruction principally of the aircraft carrying nuclear weapons and missiles and also of assembly bases and nuclear weapons storage areas; in the air support of troops-it has become the destruction of atomic artillery, various missile equipment, and of highly mobile, constantly maneuvering enemy reserves.

There was a particularly sharp change in these tasks due to the appearance of missiles of various designations in the armament of troops; as a result, front bombers and fighters began to execute their basic missions in conjunction with the missile troops and to concede to missile troops the main role in the use of nuclear weapons against stationary surface targets and against aerial targets.

By dint of these circumstances, front aviation, having conceded the main role to missiles, began to have only a part in the performance of a number of tasks - in the struggle with the means of aerial and missile attack, in the screening of troops and installations of the rear area of the front, and in the struggle with the enemy's reserves. The special province of front aviation operations remains air support of troops and the conduct of aerial reconnaissance.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

It is essential to state a number of new situations in the combat use of front aviation in ground troop operations. The struggle with enemy means of aerial and missile attack is now planned on a frontal scale, since the missile troops of the front take an active part in it in addition to aviation. Upon aviation falls the principal responsibility of destroying newly detected enemy means of aerial attack, i.e., those targets which are on the move and which will not be destroyed by missiles. The performance of this task by aviation will be resolved by the method of calling up aircraft from a position of "ground alert" or "airborne alert".

In screening of troops and installations of the rear areas of a front, new conditions have also been created which permit more effective resolution of this problem. The more important installations of the front are screened by antiaircraft missiles. However, troop, army, and front antiaircraft guided missiles are still able to destroy only the aerial targets located at insignificant distances from the missile positions; these means cannot destroy enemy missile mother aircraft at the limits from which they drop their missiles of the "air-to-surface" class. Fighter-interceptors, with their high maneuverability, are capable of meeting the aerial enemy and destroying him with guided weapons while he is still on distant approaches to the line of the front and to the installations being screened.

Taking into consideration the combat characteristics of antiaircraft guided missiles and of fighter aircraft, it is advisable to organize cooperation between them along the following lines.

First, zones of operations in area and altitude must be delineated between guided missiles and fighters. In doing so, it is desirable to assign to fighters a zone of combat operations ahead of the front line to the depth of possible interception within the radius

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

of operation of a pair of fighters, i.e., beyond the range limits of antiaircraft missiles (ZUR). When operating in the same area with ZUR, it is advisable to assign low altitudes to fighters wherever guided missiles are still limited in their operations.

Secondly, it is necessary to distribute targets of operations between fighters and antiaircraft guided missiles. Fighter-interceptors must destroy principally mother aircraft, cruise missiles, fighter-bombers, military transport aircraft, helicopters and aerial balloons, antiaircraft guided missiles, cruise (krylataya) missiles and pilotless missiles (samolet-snaryad), and also all the other manned and pilotless means that manage to break through the covering screen of fighters into the air space of the front.

Thirdly, it is necessary to set up demarcation of areas of operations between the air large units that cover the troops and those that cover installations in the rear area of the front. Taking into account that under the new conditions a front air army may have no more than two fighter divisions, it is advisable to assign one division or a major part of its forces to cover the front tank army which is operating ahead and out of contact, and the second division - to cover the other troops of the front and the installations in the rear areas. Further, it is advisable to set up demarcation of operational areas between the fighter divisions.

In air support of ground troop operations, the need to use aircraft against mobile targets becomes especially clear, since they do not all have precise coordinates, and the majority of them do not produce a clearly defined radar contrast.

In this connection, it has been deemed expedient to carry out air support of combined-arms armies by a centralized method of allocating to armies, in

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

accordance with the decision of the front troop commander, a definite number of flights (vylet) of fighter-bombers with nuclear bombs, without making the fighter-bomber subunits and units subordinate to the army. Support of the tank army that is operating separately from the main forces of the front is best accomplished by allocating designated aviation units of bomber and fighter-bomber aviation for this. The basic type of fighter-bomber and bomber operations in the air support of troops will be the method of operations on request.

From the above-mentioned facts it is possible to conclude that the basic method of operation for all types of aviation in the execution of combat missions under the new conditions is the method of operations with subunits and small groups of airplanes called up for air support from the command, or forward, control post from a condition of ground or air alert. Along with this, front aviation will participate in the execution of massive nuclear strikes against missile, air, and other enemy means of attack, not on the scale of an air army, as it was before the appearance of missiles, but on the scale of a front. This means that in modern conditions the massive strike becomes a front function.

A number of new postulates have also arisen in the conduct of aerial reconnaissance. The establishment of the reconnaissance mission has become an integral part of the operational decision. By its nature, aerial reconnaissance simultaneously fulfils, it would seem, two missions. The first and main one - the detection of enemy missile and nuclear means of attack, with the aim of ensuring direct effect on them by the missile, aviation, and artillery forces. The second mission - the continuous observation of all of the enemy's forces and weapons with the aim of planning combat operations for the following 24-hour period, day or night.

Such are the new concepts and characteristics which have been determined recently in training exercises which were carried out by the air forces, both independently and jointly with the ground troops.

New Developments in Operational Art and Tactics

by

Lieutenant-General V. Baskakov

In recent times the assertion has been growing continually more definite and more persistent, and is now deeply rooted, that the fundamental tenets of strategy, of operational art, of tactics, and of the structure of the armed forces, based on the experience of the last war, cannot ensure victory under modern conditions, and need radical revision. The reason for this is the wealth of material that has been accumulated by testing nuclear weapons - the basic and decisive means of routing the enemy in a future war - and also the experience of command-staff exercises, games, and drills with troops and from military-scientific research on the organization and conduct of an operation and of a battle. All this permits a practical review of the tenets that existed previously, and working out and basing new positions in military art in accordance with modern conditions.

In this respect, Marshal of the Soviet Union V. D. Sokolovskiy's article /footnote missing/, in which a serious and profound analysis is given of the nature of a future war, taking into account the employment of nuclear, chemical, and bacteriological weapons, has especially important significance, many tenets of the past are decisively reconsidered, and concrete problems in working out the strategy of the next war are advanced.

It is essential to recognize that although atomic weapons have already been studied for many years, we often still continue to employ former tenets in theoretical operational studies and to apply them to modern conditions. If one compares the concepts of certain operational studies and exercises, and the decisions made according to them

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

for a front and an army, with the concepts and decisions for an operation adopted by commanders of troops of fronts and armies in the last war, it is not difficult to be convinced that these concepts and decisions often coincide almost completely in their aims, forms of operational maneuver, and methods and means of defeating the enemy, and are very similar to one another. There is some difference only in the tempos of offensive, in the width of zones, and in the fact that now the absence of a continuous front is permitted.

So, on the one hand, we acknowledge quite definitely the decisive role of nuclear weapons and other means of mass destruction in the organization and conduct of an operation aimed at the complete defeat of the enemy; on the other hand, we continue to organize and plan an operation according to the methods of the last war. This obvious contradiction in the theory of operational art may, without exaggeration, be called a crisis. A correct evaluation of the role of nuclear weapons enables this contradiction to be resolved through discovering new forms and methods of armed combat and operations, and of the conduct of battle under modern conditions.

In connection with the radical alteration already recognized in the role of the types of armed forces and arms of troops in bringing about the complete defeat of the enemy, let us consider the aims, nature, and essence of a modern operation, the principles of using nuclear weapons, and other, in our view extremely important, problems.

Thus, before the appearance of nuclear weapons the main role in defeating the enemy belonged to ground troops, and as their basic operational-tactical form of organization - to divisions. In the last war, the infantry and armored divisions of ground troops were the striking force for defeating the enemy in an offensive and the basis of combat stability in defense. The destruction of divisions generally meant the complete defeat of the enemy, so the purpose of each operation was the encirclement and destruction of his main groupings of ground troops.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

After the defeat of the divisions, neither the aviation nor, even less, the artillery of the enemy, could have a decisive influence on the operations of the troops.

In connection with what has been stated, the well-known appreciation of the decisive significance of divisions of ground troops, advanced by I. V. Stalin, as one of the main constant factors deciding the fate of a war, was absolutely correct only for the last war. That is, "the quantity and quality of divisions" of ground troops at that time basically determined the military power of the opposing sides.

Under modern conditions, nuclear/missile weapons are the main means of destroying atomic weapons, ground troops, and other forces and weapons of the enemy. Therefore, one of the main aims of an operation in a future war must be, as the first priority, to deprive the enemy of nuclear weapons, the destruction of nuclear warheads and the means of delivering them to the target, but not the destruction of his divisions. This aim may also be attained by employing nuclear weapons alone.

Today, to defeat the enemy completely means wresting nuclear weapons from his hands, depriving him of nuclear power, or decisively undermining the possibility of restoring it. An enemy, having lost his nuclear weapons, irrespective of whether or not he has a sufficient number of divisions of ground troops, will already be unable to organize his defense, much less organize decisive offensive operations, and will be forced to capitulate before the threat of total destruction.

The proposition set out here is so important and basic that it can radically change not only the aims and tasks, but also the nature, of operations, and requires a quite different solution to all other problems of the organization and conduct of operations and of battle in the future. While operations were conducted previously by the forces of two or three, or even of one, front, now they will have a much wider scope and most likely will be conducted simultaneously on several strategic axes or theaters of military operations with all

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

the forces and weapons at the disposal of the opposing sides. Operations will be carried on until all enemy forces on a given continent have been totally defeated. Therefore, the scale of an operation will have nothing in common with the scale of operations in the last war. The depth of operations will not be limited to four, five, or six hundred kilometers, but will increase to at least twice this amount.

On a number of axes, where by employing nuclear weapons great destruction and devastation will be achieved, the tempo of advance of ground troops will be determined by the movement capability of the troops and will approximate the length of a day's march. However, it is extremely necessary to take into account constantly that for ensuring movement in these areas, measures will need to be taken for surmounting vast zones with high levels of radioactive contamination of terrain and with great destruction. On other axes, where the scale of employing nuclear weapons will be less, the tempo of advance may be correspondingly somewhat lower.

The essence of operations will amount to the following: organizing and delivering nuclear strikes by the forces of missile troops and aviation for carrying out strategic, operational, or tactical tasks; the employment of chemical and bacteriological weapons; moving divisions, corps, and armies of ground troops forward on selected axes into enemy territory, with the purpose of exploiting the results of nuclear strikes, completing the defeat of the remaining enemy forces not destroyed by nuclear weapons, and the final disruption of his attempts to continue the delivery of nuclear strikes; and organizing the protection of friendly troops from strikes of enemy nuclear weapons.

In connection with the above, the basic content of planning and preparation for operations will amount to organizing the employment of nuclear weapons. It is pertinent to define the general principles and to consider the concrete forms of organization of the operational employment of nuclear weapons.

The basic principle of employing nuclear weapons, in our view, must follow from the fact that they cannot and must not be used any

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

longer as a means of supporting the operations of divisions of ground troops. Nuclear weapons must be considered and used as an independent and decisive means of defeating the enemy.

Up to the present time, in theoretical studies and command-staff exercises, nuclear weapons have been planned and employed just as a means of support. For example, in the exercise in the autumn of 1959, the "East" employed 82 percent of its atomic warheads in direct support of the conduct of combat by divisions of ground troops, and only 18 percent for the destruction of means of nuclear attack and for hitting other enemy objectives. Can such employment of nuclear weapons really be considered advantageous? Does it answer the problem of depriving the enemy of the capability for employing nuclear weapons? Of course not. More than that, such employment is harmful, as essentially it means squandering the most powerful weapons of the present time on targets of secondary importance and permits the enemy to preserve the means of nuclear attack.

It is not for supporting a partial advance of this or that division and neutralizing an ordinary strongpoint that these weapons must be used, but for defeating the main forces of the enemy, and first and foremost the means of nuclear attack. Very much will depend on how far this basic proposition is perceived and understood. According to our profound conviction, this is the guarantee of success in operations.

Nuclear weapons must be used purposefully and en masse. This means that, first of all, for the total annihilation of enemy nuclear means, and then of the main grouping of his ground troops, aviation, and naval forces, an absolute majority of the nuclear warheads must be employed.

It is hardly necessary to prove that with nuclear weapons it is possible not only to annihilate individual objectives and targets but also to carry out tactical, operational, and even strategic tasks. With nuclear weapons it is possible to rout entire formations /obyedineniye/ and the main forces of the operational groupings of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

enemy ground troops, including their own nuclear weapons and airfields which are located over a considerable area and in great depth. Nuclear weapons must be employed suddenly, effectively, and economically, i. e., so that each burst should inflict maximum losses on the enemy and so that all the destructive properties of the burst itself and radioactive contamination of the terrain are used in the most advantageous manner.

Based on the general principles of employing nuclear weapons, with the object of obtaining a common understanding of the methods of their operational use and a simplification of planning methods, it would be advisable in our view to establish a separation of nuclear strikes into concentrated and individual nuclear strikes; in this, the former, depending on the importance of the tasks and goals they carry out, should be subdivided into strategic, operational, and tactical nuclear strikes.

A strategic concentrated nuclear strike is a series of most powerful nuclear bursts, directed at carrying out strategic tasks such as: the neutralization of ballistic missile bases, the annihilation and destruction of the main economic and political centers of the enemy, the crushing of his atomic industry, military bases, and other objectives.

An operational concentrated nuclear strike must be a series of nuclear bursts, delivered simultaneously or in succession by several salvoes with the purpose of carrying out operational tasks. These tasks may be: the disruption of the enemy's concentrated nuclear strike and the annihilation of his means of delivery, assembly bases, and reserves of nuclear warheads in the immediate zone of the front; the rout of a strike grouping of the ground troops, the destruction of aircraft and naval forces of the enemy; the destruction of second echelons or large operational reserves of a group of armies of the enemy and, as first priority, the annihilation of their nuclear weapons; the disruption of control and the work of the rear, the destruction of communication lines, ports, enemy bases and so on. Depending on the situation, an operational concentrated nuclear strike may coincide in timing with a strategic nuclear strike, which will be a characteristic

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

feature of operations in the initial period of war.

A tactical concentrated nuclear strike may be delivered with the purpose of routing immediate reserves, neutralizing the tactical depth of defense and the enemy nuclear weapons located in it, destroying airborne forces landed in our rear area, and also carrying out other tasks of a tactical nature.

An individual nuclear strike consisting of single or of group nuclear bursts is intended for the annihilation, neutralization, or destruction of individual enemy targets or objectives from day to day during the course of an operation, as the need arises.

A concentrated nuclear strike must be planned as an independent and most important stage of an operation, and its organization and execution are very complex and responsible matters. Such strikes, depending on the situation, may be differentiated according to the purpose of their delivery, yield, and duration, and may have the most varied plans or schemes. Military operations will start, as a rule, with concentrated strikes. It is convenient to call the one with which an operation starts the initial strike. Strikes will also be carried out during the course of a war up to its final conclusion. In connection with the considerable special features in the organization and execution of concentrated strikes, it is advisable to divide them into preemptive and counter strikes.

Such a division of nuclear strikes, in our view, is convenient for solving problems connected with the operational use of nuclear weapons. The concept of a "missile operation", on the other hand, it seems to us, fails to express fully the operational aims of this measure. The concept of a "strategic nuclear strike" would define its content considerably better. The fact is that the missile is only a means of delivering nuclear weapons to a target. In a number of instances, apart from missiles, the carrier of an atomic charge may be aircraft. In any case, the heart of the matter is not in the missile or the aircraft but in the charge itself and the burst emanating from it.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The next problem that has arisen in the operational art, in our opinion, lies in a categorical rejection of the basic principle of the operational art of the past - the principle of determining the main strike and selection of its axis, and the concentration on that axis of the main part of the forces and weapons of the front and the army.

In the last war, when complete defeat of the enemy lay in the destruction of divisions of his ground troops and was carried out in the main by the combat of our divisions, it was impossible to achieve success, either in the offensive or on defense, without selecting the axis of the main strike and concentrating the main forces on it. This had special importance when breaking through the enemy's defense, when opposite one defending division the efforts of two, and sometimes even three, divisions were concentrated, and manifold superiority in artillery, tanks, and aircraft was built up. Such a concentration of forces on the axis of the main strike, together with the extremely weak overall maneuverability of troops at that time, naturally ensured a breakthrough of the enemy's defense in the selected sector, and made it inconceivable, as a rule, for the enemy to hold zones and lines on other axes.

In this way, the principle of concentrating the principal efforts on the axis of the main strike, selected so that this axis should lead to the enemy's most vulnerable point, and the provision on this axis of double or triple superiority over the enemy in forces and weapons, was the basic principle of operational art in the past, and corresponded to the level of development of armament and combat equipment and ensured the successful execution of operations.

But can this principle remain basic in modern operational art? Does it conform to the nature of an operation and of battle being conducted under conditions of the massed employment of nuclear weapons? In our view it cannot, for two main reasons.

Firstly, nuclear weapons will play the main role in defeating enemy troops. Even to talk of concentrating the main efforts of nuclear weapons, i. e., of the employment of a neutralizing

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

quantity of nuclear bursts on an axis, even on the main one, is not only incorrect but simply absurd. With this method of delivering strikes, a considerable number of enemy troops, his corps, and divisions located beyond the boundaries of the selected axis will remain unaffected, and in the area of the burst there will not be a target deserving attention.

As an example one may cite the decision taken by the commander of the 18th Army of the "West" in the war game conducted in February 1959 in the Military Academy i/n M. V. Frunze. According to the situation on the morning of 20 July (diagram 7 of the critique materials of the game), the main forces of the 3rd Tank Army of the "East", composed of two tank and one heavy tank divisions, were in one limited area, a fourth division, operating on a broad front, covered the left flank of the Army, and the right flank of the Army was covered by an airborne division. In this situation it seemed quite clear that a large portion of the nuclear warheads should be brought down on the main grouping of the tank army with the purpose of routing it. In practice, however, the very opposite occurred. By decision of the commander of the 18th Army, all 11 warheads were employed against the divisions on the flanks of the 3rd Tank Army, and not one strike was delivered against the main grouping of its forces. As a result of this, the main forces of the tank army, not having come under the enemy nuclear strike, continued to develop their offensive without hindrance and carried out their assigned task.

This, to say the least, strange decision, was taken, obviously, because we still underestimate the role of nuclear weapons and their capabilities, while, at the same time, we overestimate the role of divisions of ground troops in a modern operation. In this decision there was very clearly reflected the tendency to employ nuclear weapons simply as a means of supporting an offensive by ground troops, and the main hopes were evidently put on the results of their operations. Adherence to the principle of concentrating the main efforts on strikes on selected axes, which, in the example given, the ground troops of the "West" were preparing, played a considerable, if not the main, role here.

[redacted] 1.3(a)(4)

[redacted]

[redacted]

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

Secondly, to concentrate the main part of the divisions of a front, army, or even a corps and the means of their reinforcement, on no matter what axis, including the main one means taking a risk, and not only taking a risk, but simply from the start giving the opportunity for these troops to be defeated, as the enemy will certainly endeavor to take advantage of such an opportunity for the effective employment of his nuclear weapons against the grouping most threatening to him.

The example cited by us is undoubtedly a minor one, but it has been taken because it clearly reflected the failure of the principle of concentrating efforts on axes to conform with the means of conducting modern operations and battle, and the recognized harmfulness of employing this principle in the training of our cadres for a future war. Therefore, modern operational art, in our opinion, can no longer employ as a basis the principle of the main strike, selection of its axis and concentration on it of the main efforts of the troops, as this principle no longer conforms either with the level of development of the armed forces or with modern military theory.

Undoubtedly, the principle of concentrating the principal effort on the main axis resulted from a most important tenet of dialectical materialism - the doctrine of the main element- and was, as it were, its interpretation in the theory of operational art. Therefore, it cannot simply be rejected, but must be replaced by a new principle, which, in our view, must become the principle of concentrating the main efforts for destroying the nuclear means and main grouping of troops of the enemy. This principle takes into full account the present level of development of the means of armed combat. It not only permits, but even compels the use of the main mass of nuclear weapons for the annihilation of enemy nuclear weapons and the route of the strongest main grouping of his ground troops, naval forces, and aviation. The divisions of the ground troops have every opportunity of bringing up their units from various axes to the area where the main forces of the enemy are; and of committing them to battle in those sectors where it seems appropriate in a particular case, in order to achieve success and not to expose friendly forces to a destructive enemy nuclear strike.

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Recently, we have frequently been considering the problem of where to deliver the main strike - on a strong or a weak point of the enemy defense. This problem, absurd in itself from the point of view of conducting operations in the age of nuclear weapons, in view of keeping the outdated principle of concentrating the principal efforts on the main axis, has now led to an impasse. Indeed, if one is to deliver a strike on the strongest point of the enemy defense, then it is possible to employ nuclear weapons successfully, but the ground troops are placed in an unfavorable position. But if one delivers a strike on the weak point of the enemy defense, then conversely, the divisions of the ground troops can select favorable flank, and generally more successful, axes, but nuclear weapons will have to be employed on targets and objectives of minor importance. What is better then, what should one sacrifice - the advantages of using nuclear weapons or the convenience of operations of ground troops?

In our view, neither one nor the other can be acceptable. One ought not to sacrifice either the advantages of employing atomic weapons or the convenience of the operations of divisions of ground troops. The only thing one should really sacrifice is the principle of selecting the axis of the main strike and concentrating on it the main efforts of fronts, armies, and even divisions. The necessity has arisen for introducing clarity into this question, lest our commanders and staffs be completely disoriented.

The problem of removing the sharp distinction between the concept of operational defense and operational offensive deserves consideration.

Previously, when divisions of ground troops were the main combat force of the two sides, defense and offensive were fundamentally different methods of operations, in each of which definite independent tasks were carried out. Defense ensured holding large fronts and territories with comparatively insignificant forces, and made it possible to free the necessary forces for an offensive. The offensive, as the main type of combat operations, was the principal means of decisively defeating the enemy and of seizing the initiative.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Under conditions of the massed employment of nuclear weapons, obviously the purely classical type of defensive and offensive operation will disappear. The success of an offensive operation, for example, will depend not only on the correct organization of the offensive itself but on how skilfully are decided the problems of cover and protection of friendly troops and means of mass destruction from destruction by enemy nuclear weapons. Elements of defense, such as security of the flanks and points at which flanks meet, consolidation of occupied lines during the course of an offensive operation were already being practised in the last war, and began to penetrate into the offensive particularly vigorously in the postwar period. The system of modern antiaircraft defense appeared and is being improved all the time.

It is quite clear that it is now impossible to plan an offensive operation without providing at the same time for measures for the defense and reliable protection of the main forces and weapons of the offensive troops from enemy nuclear weapons up to the beginning of the offensive, and consolidation of lines and repelling counterstrikes during the course of it. These measures must become one of the main component parts of the general operational plan of offensive.

It is also the same on defense. Its object will consist in the concealment of the main forces of nuclear weapons, ground troops, naval forces, and aviation, and providing for their protection from enemy nuclear weapons. Stability of defense under modern conditions is based on the massed employment of nuclear weapons with the decisive purpose of defeating the main grouping of enemy troops and the means of enemy nuclear attack. Without this, the defense is powerless and cannot carry out its tasks. But at the same time, insofar as nuclear weapons will be employed, and the destruction of the attacking strike force achieved, it is senseless not to make use of these results and to continue to go on sitting on occupied lines. It is natural, under these conditions, to go over to the offensive, even with very limited forces of ground troops, immediately after nuclear strikes have taken place. Operational defense, which counts on the maximum use of nuclear weapons, cannot now be considered without going over to the offensive

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

All this points to the fact that nuclear weapons are eliminating the distinction between operational offensive and operational defense. There will no longer be clearly defined breakthrough sectors, offensive zones for operational formations, and defense with a developed system of solid positions and zones on a front of considerable width.

The difference between the conduct of an offensive and the defense, in our opinion, will persist only in tactics. Divisions and regiments will, as before, receive tasks for the offensive and the defense and carry them out, taking into account the special features of operations when nuclear weapons are being employed.

A feature of no small importance in modern operations will also be that the rear areas of fronts and the rear of the country as a whole, with its economic and political centers and manpower resources, will be subjected from the very beginning of the war to the most powerful effects of enemy nuclear, chemical, and bacteriological weapons, which will seriously complicate the process of mobilizing troops and conveying them to the front, and also material support for operations. It follows from this that border military districts will have to initiate military operations with those forces and weapons which they had at the beginning of the war and which they can save from enemy action.

As far as internal military districts are concerned, their role and the nature of their activities are being abruptly changed in comparison with the last war; under these conditions they will be forced to take part immediately in active combat to frustrate enemy strikes and eliminate their consequences. For this purpose, they must have all necessary means at their disposal; in particular there must be concentrated in their hands all the means of antiaircraft defense (PVO), local antiaircraft defense (MPVO), etc. Dispersal of these means in various organizations can only make the situation worse.

We feel that a special type of operation must be developed - operations of an internal military district. For training generals, officers, and staffs of internal military districts in the conduct of such operations, appropriate command-staff exercises and games

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

must also be carried out, in which the problems of troop operations must be worked out under conditions of an enemy attack employing nuclear, chemical, and bacteriological weapons on the territory of the district.

The next problem in operational art, in our view, consists in the employment and the nature of operations of the ground troops themselves. As we have already ascertained, their role will amount to the most advantageous and effective exploration of the results of employment of nuclear weapons, and will be completely in line with the general concept of routing the opposing enemy forces. The tasks of large units of ground troops and the means of reinforcing them will now result from the aims of completing the rout of an enemy being subjected to nuclear strikes, advancing into and capturing enemy-held territory, conclusively depriving him of his capability to employ nuclear weapons, and maintaining the stability of the operational situation of friendly troops. At the same time, the achievement of the necessary surprise and effectiveness of the nuclear strikes being delivered and the endeavor to exploit the results of them to the maximum with ground troops and aviation must be made fundamental in organizing coordinated action.

At the same time, the massed employment of nuclear weapons cannot fail to result in changes in the operational structure of troops and a revision of the role of echelons and the methods of increasing efforts for routing the main forces of the enemy.

In the last war, an absolute majority of the troops of armies and fronts was in their first echelons. Can this position be maintained now? No, it cannot. Nuclear weapons make it possible to neutralize effectively the troops of the enemy's first echelon in certain sectors, and in a short time to break through the defense in these sectors, with a powerful first echelon which is smaller numerically. Therefore the tendency is growing immeasurably of deploying operational echelons of ground troops deeper, to have more forces and weapons in the depth, and to reinforce second echelons and reserves considerably in order to be able to increase the efforts of the first operational echelon.

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In our view, the method of intensifying efforts in an operation on those axes where the most favorable or the most difficult situation has arisen, must also be fundamentally changed. The intensification of efforts must now be carried out by small groups of troops not larger than a division. In this connection, second echelons of armies must consist of tank and motorized-rifle divisions, and the second echelons of fronts - of corps and divisions. It is not advisable now to create second echelons of fronts in the form of a combined arms or tank army, as it is simply impossible to commit to battle a whole army (and still more a reserve front) without incurring serious losses, which the enemy is now able to inflict by employing nuclear weapons.

Let us take as an illustration an example from the same war game carried out in the Academy i/n M. V. Frunze. By the time that the "West" knew about the concentration and movement of the 3rd Tank Army of the "East", the "West's" 18th Army alone had 40 nuclear warheads with a total yield of up to 1000 kt, and no less than 15 warheads could be used rapidly on the "East's" 3rd Tank Army. In addition, the group of "West" armies also had a large number of nuclear warheads at that time, of which only 23 warheads were used for delivering strikes on the area of the hills of the "Thueringen Forest", with the aim of creating there zones of high radioactive contamination. If all these warheads had been used with a definite purpose on the troops of the "East's" 3rd Tank Army, especially when it had not moved up to the "Thueringen Forest" hills, then this army would undoubtedly have been completely routed and could not have been committed to battle. The exercise could have been concluded at this point.

In defense, divisions of the first operational echelon which are in direct contact with the enemy, will as a rule be better reconnoitered by the enemy. Therefore commanding officers of and commanders of armies will undoubtedly also endeavor to conceal from the enemy their main forces operating in the first echelons, having at every slightest available opportunity concentrated their efforts on positions deployed in depth, on the strength of which even the first operational echelon will be considerably more dispersed in depth.

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

In our opinion, evaluating the power of atomic weapons and their possible operational use, it must be considered that second echelons and reserves of armies and of a front must now consist of more than 50 percent of all their component forces and weapons. In connection with this, the overall density of troops in first echelons will also be many times less than it was in the last war.

In order to evaluate better the effect of employing nuclear weapons and other means of mass destruction on the nature of operations and combat, let us consider several basic problems of the organization and conduct of a defensive and an offensive operation.

In principle, defense, in our opinion, must be constructed in the following manner: divisions of the first operational echelon cover the main axes and ensure observation on the remaining axes. Reconnaissance subunits are in direct contact with the enemy, then come the troops detailed for combat in the security zone, further the units defending the forward position, and, finally, the main line of resistance.

The question arises, is such cover adequate or should one not also, under modern conditions, organize such a multi-zone echelon-in-depth defense as there was in the past? Could the enemy, even without nuclear weapons, unexpectedly turn to the offensive with ground troops, break this sparse cover and successfully develop an offensive in depth?

In our view, such a structure of cover is adequate. If the enemy really tries to deliver a strike without having neutralized the nuclear weapons of the defense, i. e., without having thoroughly organized the operation, then he will receive a counter-nuclear strike of such strength that it will not only paralyze any offensive of his, but may bring about the total loss of troops assigned for it. On the other hand, will the reliability of the cover be increased much if a "normal" defense is organized, as it was in the last war, with an average density of 10 to 15 kms per division? Are there really no weapons now, capable of neutralizing any sector in this defense that is essential for a breakthrough at any place and at any time?

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

The success of covering operations of troops will now depend not on how many divisions of ground troops are defending the main zone of defense, or whether there is such a zone at all, but to what extent the attacker will succeed in neutralizing the nuclear weapons of the enemy. If this task is not carried out by the attacker, then comparatively small forces, reinforced by the maneuver of tactical and operational reserves, are quite adequate, by the massed use of nuclear weapons, to frustrate the development of an offensive by enemy ground troops into the depth of the defense.

Such an organization of cover, in our view, will now be typical in all cases preceding the beginning of active combat operations. Such cover will replace the operational defense of the past.

Let us turn to the problems of the offensive. The organizational beginning of an offensive operation of a front is a General Headquarters (Stavka) directive in which the tasks, composition of forces and weapons, and the time of carrying out the operation are defined. In contrast with the past, there is now no need to define in the General Headquarters directive the axis of the main and other strikes, or to stipulate the amount of forces to be allotted to these axes. At the same time, the necessity of indicating the following arises: which nuclear strikes will be delivered by the means of General Headquarters on the axis of operations of the front, when and how the long-range enemy nuclear means which are beyond the range of the means of the front will be neutralized, and whether the means of the front will be called upon to carry out the indicated strategic tasks.

In our view, the content of the decision of the commander of troops of the front (army) for carrying out an operation must be changed materially. A resolution of the following problems must be included in it: - determining the maximum required number of nuclear warheads and the selection of their most advantageous yield, determining the points of concentration and time periods for readying nuclear warheads for use; - establishing methods for neutralizing and destroying nuclear means and also for routing the main groupings of ground and naval forces and aviation of the enemy; determining the number of operational and tactical concentrated nuclear strikes, their tasks, compo-

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

sition of forces, and time of delivery; a detailed working out of the initial concentrated nuclear strike; - determining the lines of the immediate and subsequent tasks arising out of the planned nuclear strikes; - making the decision to use ground troops (and naval forces on a maritime axis) and aviation for completing the rout of the enemy, and the time of their move to the lines of the immediate and follow-up tasks; - determining the tasks of the airborne forces and troops designated to be dropped in the rear of the enemy from the air; - establishing methods of cover from enemy strikes for friendly troops and weapons, above all nuclear weapons; - allocating tasks to operational formations and large units.

As is evident from the list given here, the basic content of a decision for a modern offensive operation must include determining the problems in employing nuclear weapons, and of these one of the main and most complex is the organization of the initial operational nuclear strike, the main purpose of which is to destroy the nuclear means and neturalize the main grouping of ground forces and aviation of the enemy.

The destruction of enemy nuclear means is the most important and, at the same time, the most difficult of the tasks. The fact is that with the means of reconnaissance available at the present time it is difficult to discover the location of enemy nuclear weapons. Attempts to develop a special device which would permit determining at a considerable distance the location of depots of nuclear warheads, assembly workshops, positions of missiles, and delivery aircraft, have not yet, according to data in journals, given favorable results. However, this does not mean that with the available .../one line missing/. In our view a thorough analysis of all intelligence data received from all sources can ensure the discovery of the location of the main part of the enemy's nuclear means. But this study must be very carefully and thoughtfully organized. For such a study and analysis of reconnaissance data, it is essential right now to have special groups for evaluating targets in the staffs of fronts and armies. In addition, it is necessary to continue persistently to search for new methods of getting intelligence on enemy nuclear means. In this, the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

main direction must be taken not toward piloted reconnaissance aircraft, but to the use of pilotless aircraft-missiles (samolet-raketa) for this purpose, and also in the creation of a device which transmits an image during flight, determining the coordinates of objectives, precisely expediting the development of film and photographs greatly, etc., i. e., wholly answering the requirements given for reconnaissance of the enemy's nuclear weapons.

Nuclear means and missiles must be located only in well-prepared areas before the beginning of an offensive. Commanding officers of all levels must remember that if it is possible to weaken the consequences of the effect of the shockwave by means of dispersion of troops, it is possible to save the troops from penetrating radiation only by giving them cover in shelters and blindages. All movements must be carried out in the shortest possible time, at high speed, and with a considerable dispersion of troops.

The beginning of an offensive must be timed to the execution of the initial operational nuclear strike. Divisions of the first echelon must begin their move forward from shelters and areas which are completely prepared from the engineering standpoint under the cover of the initial nuclear strike or after the delivery of such a strike by the enemy. The attacker must strive to guess the enemy's intention to carry out a concentrated nuclear strike, and to frustrate or weaken it as much as possible.

During the course of an operation the reinforcement of appropriate sectors of the front must now be carried out by employing nuclear weapons and maneuver by trajectory (manevr trayektoriyami) and to a lesser degree by transferring the reserve of the front or the reserves of neighboring armies, to complement one or another army. An offensive by divisions of ground troops will be carried out along the whole zone of the front on individual axes in accordance with the requirements of the Field Service Regulations. The axes of operations of a division must be selected so that they ensure an adequate dispersal of forces and of the movement of units toward corresponding enemy groupings of troops, and should also lead into the operational depth of his defense.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

In conclusion, it is desirable to emphasize once again the idea that the success of an offensive operation will, in the final analysis, depend on whether the attacker is able to neutralize substantially the enemy's nuclear weapons. If he is unable to ensure this, the offensive will be frustrated no matter what measures he may undertake. That is why it is now impossible to conduct operations with the forces of a single front, as neighboring enemy armies or groups of armies can ensure a concentration of nuclear strikes that will stop any offensive by maneuvering means of delivering nuclear weapons. For these same reasons, offensive operations of a group of fronts must be secured by the conduct by General Headquarters of a strategic nuclear strike or a missile operation with the object of neutralizing the enemy's strategic nuclear weapons means.

MEMO FOR THE RECORD 6 Feb 1962

SUBJECT: Discussion between SR/COP, CSR/9, DCSR/9, [redacted] 1.3(a)(4)
[redacted] re: SR/COP's European trip, 1-5 Feb 62, and SR/COP conversations with [redacted]

1. SR/COP stated that [redacted] agreed that [redacted] high volume of document photography was the greatest risk to the operation. However, [redacted] 1.3(a)(4)
does not feel that [redacted] would accept KUBARK's suggestion to reduce either this activity or the number of personal contacts within [redacted] for the following reasons:

a. The personal contact with someone he knows is very important to [redacted] subjectively. 1.3(a)(4)

b. [redacted] has not accepted previous suggestions to reduce the number of personal contacts.

c. The case officer teams were not able to hold down [redacted] on the number of personal meetings during the Paris phase. (Note: CSR/9 took exception to this, noting that [redacted] himself was pushing for more meetings.)

d. [redacted] is loath to use dead-drops because of security considerations, as well as because he derives satisfaction from personal contacts. (Note: CSR/9 observed that this was true so long as [redacted] had other means available to him.)

2. [redacted] noted to SR/COP that [redacted] has followed closely his requirements briefing, and extra material he has reported has been well selected, comprising materials to which we did not know he had access. He has not been passing material of low interest since the Paris phase. [redacted] feels that the introduction of new requirements normally should be avoided, as this will probably spur [redacted] to renewed collection activity, and this would be a greater risk to the security of the operation than to allow [redacted] to continue in his present method. [redacted] would therefore prefer to avoid inserting additional requirements now. While agreeing on the desirability of reducing the number of personal contacts, [redacted] doesn't believe that we presently have that kind of control over [redacted] However, [redacted] feels we have a reasonable chance to secure a reduction in the number of personal contacts on grounds of [redacted] physical condition. This would only be good temporarily. 1.3(a)(4)

3. [redacted] according to [redacted] presently has three Minox cameras in his possession. He has hidden one, and carries the other two with him, enabling him to shoot 100 frames without pausing to reload. 1.3(a)(4)

4. SR/COP met [redacted] for several hours together with [redacted] and received a favorable impression of her. She seemed fairly relaxed about 1.3(a)(4)

APPROVED FOR RELEASE
31 MAR 1992

/2

C/SR
DC/SR
SR/COP
C/SR/9
/DCOP

[redacted] 1.3(a)(4)

her part in the operation, and SR/COP stated that he was somewhat reassured about the conduct of her contacts with [redacted] 1.3(a)(4)

5. SR/COP learned from [redacted] that the personal contacts in the vicinity of the park are generally executed in the manner outlined below. [redacted] is in the park with her son, who is about 2½ years-old. [redacted] appears on the scene, and then proceeds down one of the streets leading from the area, selecting a different one each time. [redacted] follows after him, occasionally with some trouble persuading her young son to leave the piles of snow in the park. There is little vehicular traffic along these various side streets, but a fair amount of pedestrian activity. [redacted] is a plain girl and dresses in such a manner that she does not feel she is conspicuous as a foreigner in the neighborhood. [redacted] enters one of the doorways along the side street, apparently pre-selected by him before each contact, and stands behind the stair well, so that he can observe anyone coming down the stairs or through the door. (Note: On just one occasion, [redacted] apparently changed the entry he had chosen when it was suddenly entered by four people. No further incident occurred.) [redacted] enters after [redacted] and is with him about ten seconds, but sometimes more. [redacted] passes anything for [redacted] in a package of [redacted] cigarettes, and he passes material to her in a package of [redacted] cigarettes. [redacted] places the material received from [redacted] in her bag, and [redacted] pushes it down himself, being sure it is firmly in place. They always exchange a comment or two about such things as family health, etc. [redacted] always says when the next contact will be. They have never been interrupted. When meetings begin in the shop instead of the park, [redacted] follows [redacted] out to another doorway in the same manner as above. 1.3(a)(4)

6. SR/COP asked [redacted] about normal surveillance on her and her cover for action. [redacted] noted that her husband was heavily surveilled, but that she herself was seldom followed. SR/COP observed that she was probably good at detection. [redacted] cover for being in a doorway would be to adjust her clothing or tend to her son out of the cold. [redacted] has never made a record of the windows overlooking the contact sites, but feels that the normal traffic in these streets renders the whole action inconspicuous. The only contact which took place in the open was the first one. [redacted] does not discuss the contacts with her husband, but must communicate in writing for security reasons. 1.3(a)(4)

7. [redacted] expects to withdraw [redacted] and her husband from the area about June 62. He has in mind another married couple to replace them; the wife is also a former [redacted] secretary. She has three children. Two are too old for cover use, but the third will be "pram age" at her arrival in the area. 1.3(a)(4)

8. SR/COP raised with Shergold the question of making a gesture of appreciation for the work of [redacted] [redacted] thought that a "handsome present", implying cash, would be in order after she and her husband return to [redacted] SR/COP agreed, and said that KUBARK would like to share in the present. 1.3(a)(4)

9. [redacted] agrees on the need to supplement or, if possible, to swithh from clandestine meetings to meetings with a cover. [redacted] is now preparing a younger 1.3(a)(4)

officer, in an appropriate cover slot, to enter the area sometime in the fall for this purpose. His language proficiency is reputed to be high, and SR/COP speculated whether George Blake might know of him. In the interim caused by personnel changes, a slow-down on personal contacts may be required.

10. SR/COP and [redacted] briefly reflected on the possiblity of using KUBARK staffers' wives for the contacts. SR/COP informed [redacted] that KUBARK was also preparing personnel who could serve as contacts. 1.3(a)(4)

11. In answer to a query by DCSR/9, CSR/9 suggested that SR/9 should probably itself handle the debriefing of members of the Parsons-Wittemore delegation.

12. [redacted] explained the time required to pass material from [redacted] to KUBARK Headquarters. He said that there is no delay in London, because he puts the material in the next pouch to [redacted] after he receives it. However, the material may wait for nearly a week in [redacted] for the next pouch after having been delivered by [redacted] to her husband. [redacted] says that he tries to avoid sending cables to [redacted] husband outside of normal working hours, in order not to disrupt what should be normal routine in [redacted] (Note: DCSR/9 observed that [redacted] husband obviously knows of the occurrence of a contact with [redacted] very soon after it happens, and wondered how [redacted] informs him.) [redacted] has three cipher clerks in [redacted] Headquarters cleared to process [redacted] traffic, but says that there may be week-end delays, again because he does not want to disrupt a normal pattern. One of the cipher clerks, however, is always on call. 1.3(a)(4)

13. London Station, KUBARK, told SR/COP that [redacted] normally responds to any communication from KUBARK Headquarters via the same channel through which he receives it. It was explained to [redacted] that the KUBARK cable channel is preferable to [redacted] and that with KUBARK's move to its new building the [redacted] channel will be quite cumbersome. [redacted] saw the point, voiced no objection at all, and said he would discuss it with [redacted] 1.3(a)(4)

14. [redacted] has been asked by [redacted] to "begin lining up" a trip to [redacted] in March or April 62 if [redacted] does not by then appear to be coming out. In any event, [redacted] will definitely go to [redacted] about August 1962. [redacted] has a scheme for a pre-fabricated display van for making exhibits portable. [redacted] has (?) advanced him about $15,000 in this connection. Apparently this is construed as a loan on an eventual profit-making venture. [redacted] will take this van with him to [redacted] [redacted] did not raise the question of KUBARK participation in the financing of this van. 1.3(a)(4)

15. SR/COP raised with [redacted] the question of contact reports on the meetings with [redacted]. [redacted] confirmed that separate reports would be sent on any special incidents, and also agreed to furnish more detail in the routine notices; specifically, the street and number where the contact takes place. 1.3(a)(4)

16. There is nothing new on [redacted]

17. SR/COP raised with [redacted] the question of a general operational accounting. [redacted] said that he would provide one to Kubark. [redacted] also volunteered the information that he had alerted [redacted] Finance to earmark an approximated £100,000 (One hundred thousand pounds sterling) against [redacted] possible defection and resettlement. [redacted] has in mind that this would be administered to [redacted] as a trust fund, thereby provding him with a guaranteed annual income. 1.3(a)(4)

18. [redacted] prefers, for his own administrative purposes, not to change the YOGA cryptonym, unless it is causing KUBARK in confusing traffic with that in another [redacted] channel.

19. [redacted] would prefer not to issue the electronic dead-drop to [redacted] without further opportunity for [redacted] personal instruction in its use. SR/COP agreed that this would be most desirable, but advised that written instructions will be adequate in themselves to instruct [redacted] It was agreed, therefore, that one unit would be retained in the [redacted] Embassy to be passed as opportunity permits if [redacted] does not come out in the reasonably near future. 1.3(a)(4)

20. [redacted] Embassy in [redacted] is not able to provide W/T confusions to support [redacted] possible transmission on an harmonic of their frequency. It would necessitate too great a departure from their normal W/T procedures. 1.3(a)(4)

21. [redacted] is willing to go along with the proposed audio operation against [redacted] Embassy, Paris. [redacted] 1.3(a)(4)

END

Following is a verbatim translation of an article titled " The Suitability of Modern Means and Methods in the Conduct of Operations", by Major-General I. Zavyalov.

This article appeared in the 1960 First Issue of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET by the Soviets and is issued irregularly. It is distributed only within the Ministry of Defense down to the level of Army Commander. The 1960 First Issue was the initial issue of this publication.

The Suitability of Modern Means and Methods in the Conduct of Operations

by

Major-General I. Zavyalov

In all armies, the essence of the development of military art has consisted, at all stages, of researching into and of developing methods of conducting combat operations which will ensure the most effective use of the weapons available.

This task acquires particular urgency during periods when a weapon of a completely new principle is appearing which has higher combat characteristics and which calls for completely new methods in the conduct of combat operations. Such a situation has been created today by the introduction of nuclear weapons into the armament of armies.

We must recognize that if a great leap was made in a short period of time in the development of modern means of armed combat and especially of nuclear weapons, there are still many very complicated and unresolved problems in the research into and the development of methods for the conduct of combat operations.

It stands to reason that new methods of conducting armed combat must be built not on the conjectures and fantasies of individuals or on their good intentions but on a real foundation; on the material resources for war which the State and its armed forces possess with regard to the quality and quantity of the new weapons and to the other military equipment which is already available or which can be produced by the State for the conduct of a war and, also, with regard to the forces and potential of the probable enemy. Obliviousness to these requirements during research on and the development of new methods of conducting armed combat will lead inevitably to serious mistakes in the theory of military art and to adventurism in the conduct of war, as was the case, for example, with Germany in the two World Wars.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

At the same time, the theory of military art must not become simply a registrar of practical achievements. In studying and summarizing the experience of troops and the results achieved in the development of means and methods in the conduct of armed combat, military theory, like every other advanced scientific theory, must light the way for practice, must provide decisive influence on the structure of armed forces / a few words missing /----------means and methods of conducting a war. To perform a task, one must have a clear perspective before one and one must look far ahead.

Under modern conditions, military art, in theory and practice, must not go so far as to base its calculations on the idea that the entire military-political and strategic aims of a war can be attained solely with the aid of nuclear/missile weapons. This will lead to narrow mindedness in military theory, to one-sidedness in the preparation of the armed forces and in the final analysis, to the inability of the latter to perform combat tasks in the complicated situations of a future war. It should not be forgotten that nuclear weapons are, after all, a complex, expensive, and, in the quantitative sense, a limited means of armed combat. This situation obliges us to seek and to create such new methods of conducting combat operations as will ensure the most effective use of the vast combat capabilities of nuclear weapons in the first place and, with this, of the conventional means of armed combat.

Large qualitative changes have occurred in the development of nuclear weapons. They have been widely introduced in all types of armed forces and have become the basic means of armed combat. The aircraft, as the basic carrier of nuclear weapons, has yielded its place to the missile. At present, the nuclear/missile weapon has attained a level of development which has called into being a new type of armed forces - missile troops of strategic designation to whom the main role in a future war has been assigned. Thus, the nuclear weapon has already ceased to be just a means for the independent fulfillment of combat missions on any scale.

It is no longer possible to limit oneself solely to adapting the old methods for the conduct of combat operations to the new weapons.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

A bold, radical break is needed in this matter, so that the use of nuclear weapons becomes the basis of everything. This break must not be indiscriminate, needlessly disclaiming all previous experience, but reasonable.

However, we do not always take into account the changes which have taken place, and even now the mere renovation of past experience in tactical and in operational art and the adaptation of antiquated methods of conducting armed combat to the new weapons continue to persist. We will attempt to show this, using as an example the solutions of some of the questions of the preparation and conduct of modern offensive operations.

Conditions of the Preparation of an Offensive Operation

As is generally known, any offensive operation is restricted in time and space which are, in turn, determined primarily by the supply of material and technical equipment and by the moral and physical capabilities of the troops. In the past war, after the conclusion of a normal offensive operation and the performance of the assigned tasks, the troops halted, put themselves in order, and consolidated themselves along the lines which they had reached. This occurred most frequently while the defending enemy, having brought up fresh reserves, was strengthening his resistance and when the advancing troops were exploiting their offensive possibilities completely.

As a result, an operational lull of varying duration occurred, during which both sides prepared for new operations. Such an operational lull, during which preparations for a new offensive were carried out or the troops prepared for defense, was characteristic of past wars. However, even now, one comes across attempts to transfer this experience mechanically to modern conditions although such operations are no longer in keeping with the new means of armed combat.

In speaking of the first operations of the initial period of a war, one must assume that these will be primarily nuclear/missile

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

operations, directed at the complete destruction of the enemy. It is beyond any doubt that both sides, even during peacetime, will attempt to discover and to study all of each others most important targets and particularly those such as missile sites, nuclear weapons storage sites, and military-industrial and political centers. The opponents will estimate and prepare the quantity of nuclear weapons needed for the annihilation of these targets and will take every measure required to accomplish the tasks of the war with the first massive salvoes of nuclear/missiles, using fixed launch sites (statsionarnaya pozitsiya) already prepared in peacetime, and missile submarines and aviation.

In the course of such shattering blows or after their delivery, if the goals of the war have not been attained, the ground troops, who will develop offensive operations aimed at the consolidation of the results achieved and at completing the destruction of the enemy, will go into action.

Under these conditions, as a rule, the transition from one operation to another will take place without any operational lull since the preparation for a new operation will have to be accomplished while the offensive is developing. Even in cases when such a lull does occur, it will be far shorter in duration than those of the last war and will differ significantly from these in accordance with the character of the combat operations. It is surely quite evident that, with the powerful long-range means of destruction at their disposal, the belligerents will scarcely limit themselves to operations which are purely of a reconnaissance nature or to fighting to improve their positions during the preparatory period of an operation. Therefore, given that the means of nuclear attack are available, both sides will conduct aggressive combat operations even during an operational lull. They will strive to make use of every favorable moment to deliver nuclear/missile strikes, primarily against the enemy's means of nuclear attack, against his approaching reserves and against concentrating groupings of his troops, in order to disrupt the preparation of an offensive long before its beginning or to seriously weaken the enemy and thus to create favorable conditions for the successful execution of a new operation. The strength of such strikes will depend upon the availability of nuclear weapons

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and on the ability of the ground troops to perform the tasks assigned by exploit ng the results of nuclear strikes.

Modern means of combat not only permit the allocation and performance of such tasks but also require similar activity in the course of the operation as well as during the operational lull. Furthermore, given a sufficient amount of nuclear weapons, a transition to the offensive is possible even though the troops are not completely ready and although the correlation of the remaining force and weapons is unfavorable. This lack of readiness can be offset by the delivery of preemptive (uprezhdayushchyy) nuclear strikes against the enemy which will make it possible to inflict serious losses on him and to change the correlation of forces to our advantage quickly.

Incidentally, too, we still approach the appraisal of the correlation of forces in the old manner: we consider divisions, aircraft, tanks, and guns first of all and often forget that the principal advantage / a few words missing /----------in the methods of using it, in the skilful employment of these means, even though all this is more difficult to bring out and to evaluate.

Thus, the constitution of the operational lull, if one takes place, will now change completely. It will be characterized by aggressive operations by the troops with decisive goals, owing to the fact that there will apparently be no sharp distinction between the end of one offensive operation and the beginning of another. In order to avoid needless losses during the operational lull, both sides will strive to shorten it as much as possible. As a result, the preparation of a new offensive operation will now take place under different and considerably more complex conditions than was the case during previous wars. Past methodology, in this matter, is dead. However, we must take into account that such operational methods will require high combat readiness on the part of the troops both in the exploitation of the results of their nuclear strikes and in repelling possible enemy strikes.

1.3(a)(4)

The Contents of a Commander's Operational Decision

In the making of decisions on an operation, the tendency which manifests itself most noticeably is that of adapting former methods of operations to new weapons, or alternatively, new weapons to old methods. If we take the operational decisions of the World War II period or of the immediate postwar years before the adoption of nuclear weapons and compare them with modern operational decisions involving the mass employment of nuclear weapons, it is difficult in a number of cases to discover any kind of difference in principle in their content. In both cases, the activities of the combined-arms and tank formations or large units form the basis of the commander's plan for the attainment of the assigned aims of the operations. Dependent upon this, the method of using (or the tasks of) aircraft, artillery, and other means of armed combat for the support and protection of infantry and tank combat operations is determined. Today, such tasks are also given to the means of nuclear assault.

This was correct at the time when there were no nuclear weapons or when their consumption in an operation did not exceed twenty or thirty units, because the main role in the rout of the enemy and in the operation as a whole was played by the tanks and the infantry while nuclear weapons, as well as aircraft, artillery and other means of combat, played a protective role and supported the operations of the infantry and tanks. Now, with the mass employment of nuclear weapons, when they have become the basic and decisive means of destruction, when with nuclear missiles of varying designation one can perform independently any tasks in the destruction of enemy groupings, it is wrong to put these weapons on a par with conventional weapons as used to be done and to decide on the way in which they should be used in accordance with the methods of infantry and tank operations, i. e., it would be wrong to assign them to a protective role, as was done previously.

The activities of those forces and weapons which play the main role in the attainment of the goals of an operation must

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

form the conceptual basis of any decision. Under modern conditions operations by missile troops and nuclear/missile strikes on the enemy will form the basis of the troop combat activities designed to fulfil the tasks of an operation and to attain its goals. If the missile troops and nuclear weapons are allotted the main role in an operation, the methods and sequence of use of these missiles must form the basis of the plan, which aims at inflicting decisive destruction on the basic groupings of the enemy. In accordance with and bearing in mind the possible results of nuclear strikes, it is necessary to determine the sequence and methods of operations by the infantry, tanks, and other means of armed combat in order to exploit these results to the fullest for the final destruction of the enemy.

Questions concerning the planning of an operation, which must be based on the use of nuclear weapons, should be resolved in the same fashion. This position provokes objection from no one. However, in practice, during our exercises, the reverse is often done: operations by the infantry and the tanks are made the basis of the plans in these cases, while nuclear weapons are seen as means for their reinforcement and support.

Thus,past experience prevails even in this question.

The selection of the direction of the main strike. As we know, the principal goal of any operation has been and remains the destruction of the enemy. It is for this that operations are organized and conducted. In offensive operations by a front, this goal is attained by the combined efforts of all the forces and weapons called upon to carry it out by the delivery of a series of simultaneous or consecutive strikes on the enemy, most frequently in several directions. One of these strikes is the main one.

In Soviet military art the greatest importance is attached to the selection of the main strike because it is on this that the success of the operation largely depends. The determination of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the direction of the main strike depends on the goals and tasks of the operation, on the nature of the defense, on the groupings and expected methods of enemy operations, the availability and condition of our troops, the nature of the terrain, and on other conditions. The basic requirements in directing the main strike are, firstly, that the most effective use of the combat capabilities of all forces and weapons called upon for the operation is made in this direction; secondly, that the main strike is aimed at the destruction of the basic enemy grouping and that it is delivered at the most vulnerable and weakest point of his defense where maximum results can be attained with the least losses in short periods; and thirdly, that a concentration of the basic forces and means of the advancing troops is ensured in the direction of the main strike and that their significant superiority over the enemy is established.

To what extent do these requirements correspond to modern conditions for the conduct of operations and to the combat capabilities of nuclear weapons? In order to answer this question, one must take into consideration the fact that the direction of the main strike is always selected in the interests of the most effective use of the basic means of armed combat. Previously, these means, which decided the success of an operation, were infantry, artillery, and tanks. The direction of the main strike was selected in their interests and they formed the basis of the principle of military art -- deliver the main strike on the enemy's weakest and most vulnerable spot. This principle accurately reflected the capabilities of earlier combat weapons.

Why was it necessary to deliver the main strike exactly at the enemy's weakest spot? First of all, because to deliver the main strike directly on the basic grouping of the enemy made it necessary to concentrate a large quantity of forces and weapons in order to establish superiority, involved the advancing troops in heavy casualties, did not ensure high rates of advance and, as a rule, did not lead to the destruction but only to the repulse of the enemy, i. e., the goal of the operation was not achieved. Of no small significance was the fact that the advancing troops did not have the powerful long range means of destruction which

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

would have enabled them to inflict decisive destruction on the enemy by strikes carried out throughout his entire tactical and operational defense, to inflict decisive destruction on him, to paralyze the movement of his reserves, and to prohibit an organized withdrawal to occupy new defense lines. The absence of these means could only be compensated for by a rapid breakthrough in the weakest sector of the enemy's defense and by a swift movement (vykhod) to the flanks and rear of his basic forces by powerful strike groupings of the advancing troops, particularly tank, with the simultaneous dropping of airborne troops on the enemy's communications.

Finally, it is necessary to remember that the enemy, who was on the defensive, also lacked long range means with sufficient power to allow him to step up his efforts rapidly in the weakest sectors of his defense, where the advancing troops were breaking through and delivering the main strike. In the majority of cases, this could only be done by maneuvering the reserves or by removing troops from sectors which were not under attack, which took a long time. Profiting by this and possessing superiority in forces and weapons, the advancing troops most often succeeding in breaking through the enemy's defense before he could bring his reserves up into these directions.

Consequently, the delivery of the main strike against the weakest spot of the enemy's defense was dictated by the relatively limited combat capabilities of earlier weapons. It was primarily by breaking through the weakest link in the enemy's defense that the rapid movement of the strike groupings of the advancing troops against the flanks and rear of the basic enemy forces and the task of destroying them as quickly as possible could be achieved.

At the same time, an analysis of many of the operations of past wars, and of World War II in particular, also shows that in a number of cases the main strike was delivered directly against the basic enemy grouping, i. e., against the strongest sector of his defense. This happened particularly in offensive operations conducted in mountains, in deserts, in wooded and marshy areas

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and also during an advance from bases of operations on river lines. But in the process, a multiple superiority over the enemy was always established particularly in weapons for neutralization (sredstvo podavleniya).

Under modern conditions, nuclear weapons alone, without the aid of other means of combat, are able to inflict such losses on the enemy that they can seriously reduce and even completely deprive his basic groupings of combat ability and can thus ensure a correlation of forces advantageous to us. Therefore, in determining the direction of the main strike, it is now necessary to begin by considering the possibilities offered by the most effective use not of the infantry or of the tansk, but primarily of the nuclear weapons. Where, against what targets, and for the solution of which tasks would it be most advantageous to employ these weapons? Obviously, in the spot where the most appreciable losses can be inflicted on the enemy, where his system of troop control will be destroyed for a prolonged period, and against those targets which present the greatest danger to the advancing troops and which could prevent the attainment of the goals of the operation. Such targets are the enemy's means for nuclear assault, the basic strongest groupings of his troops and his control centers. The destruction of these targets will lead to a sharp reduction in the enemy's capabilities for the employment of nuclear weapons and to the disorganization of his defense in the most important directions and thus creating advantageous conditions for a swift advance by the infantry and the tanks. The bulk of the means for nuclear attack and the basic efforts of the attacking troops must be directed towards the fulfillment of such tasks.

The use of nuclear weapons against the most important targets of the enemy's defense permits the infliction upon him of such destruction that he will not be in a condition to offer any kind of serious resistance here. The surviving remnants of the enemy's forces and weapons will be paralyzed over a vast area and because of the areas devastated by nuclear strikes, the existing gaps in his defense will increase even more. This will become the weakest spot in the enemy's defense, which the ground troops must boldly

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

exploit in order to destroy the enemy completely and to develop the offensive in depth rapidly, without the execution of a complicated maneuver.

The availability at the front of nuclear missiles with a range of up to 600 kilometers now permits the simultaneous delivery of strikes throughout the entire depth of the enemy's operational formation and against his communications and his troop supply bases, thus destroying the stability of his defense and prohibiting troop maneuver, and the provision of supplies. Such strikes will oblige the enemy to use his reserves not to deliver counterstrikes against the advancing troops but to close the breaches formed in his defense and to make up the losses of the first echelon of the defense troops. As a result of the operations indicated above, the necessity for the execution of deep enveloping maneuvers by large groupings of the advancing troops, aimed at gaining the rear of the basic enemy forces and at their subsequent encirclement and destruction, has largely passed. Now this task can be more successfully performed by the rapid advance of strike groupings in the shortest direction after nuclear strikes, with the simultaneous landing of airborne troops in the enemy's rear.

To use nuclear weapons for the penetration of the enemy's weakest defense sectors and for the delivery of strikes against unimportant targets, contradicts the very nature of these weapons and leads to their unproductive expenditure. One must take into account that the defending enemy will also have nuclear weapons and that, if the advancing troops do not inflict decisive destruction on him at the proper time, making use of the whole power of their nuclear weapons, the enemy can forestall them and can wreck the advance with strikes by his own nuclear weapons.

One must also take into account that the concept of "a weak spot in the enemy's defense", in itself, acquires a completely different meaning under modern conditions. The availability to the enemy of nuclear/missiles permits him to carry out a maneuver with nuclear strikes, concentrating them in any sector of the defense.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Furthermore, the enemy will deliberately leave sectors in his defense uncovered by troops while keeping them covered by nuclear weapons in order to lure the advancing troops into this trap, and then to destroy them with nuclear/missile strikes. Even where the advancing troops are successful in breaking through the weak defense of the enemy, he will be in a position to block the progress of the advance in depth by using the nuclear weapons of his basic grouping. Consequently, sectors weakly protected by enemy troops are no longer necessarily his most vulnerable spots. Under modern conditions, the most vulnerable spots can even be those sectors with the strongest defense, if the enemy is unable to conceal them and to cover them with a sufficient quantity of nuclear weapons. When superiority of nuclear means over the enemy is present, his defense in any direction can be disorganized and weakened / several words missing / ---------- for the attainment of the aims of an offensive operation. Properly assigned reconnaissance is necessary in order to prevent nuclear weapons being used against an empty area.

In selecting the direction for the main strike, the nature of the terrain plays a role which is far from unimportant. In the past, terrain was usually selected which best provided for the use and maneuver of large masses of infantry, tanks, and artillery, and for the maintenance of close coordination. It should be said that the suitability of the terrain from the point of view of using all forces and weapons and of the advantageous delineation of the front line often determined the selection of the direction for the main strike, despite the fact that, as a rule, it was here that the enemy set up his strongest defenses.

Under modern conditions, the terrain will also be of great significance in the selection of the main strike direction. However, it is not now necessary to establish powerful groupings of troops in the most accessible section of the terrain for the penetration of a strong defense. The performance of this task is facilitated by the availability of nuclear weapons. The delivery, here, of the main strike through the mass use of nuclear weapons makes it possible to deliver decisive destruction to the defending enemy grouping, to destroy the stability of his defense, to paralyze his reserves, and to develop a swift troop advance in great depth.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

In speaking of the main strike, one cannot pass in silence over the fact that the demand still persists among us, although with various reservations, for the concentration of the basic forces and weapons in the main strike direction. Under modern conditions this demand is not only unfounded but also conceals within itself the danger of unnecessary losses caused by the enemy's nuclear weapons. Now, it is of primary importance to attain superiority over the enemy in nuclear weapons dispersing them throughout the entire zone of a front's advance. The great ranges of operational-tactical missiles permit nuclear weapons to maneuver their strikes freely and, when necessary, to concentrate these strikes in any direction and in any area , thus exerting a decisive influence in changing the situation to our advantage.

There is, therefore, no need to concentrate large forces of infantry, tanks, and other weapons in the main direction. They, too, should be dispersed throughout the entire zone of the front. However, they should be aimed in advance against those directions where nuclear strikes will be delivered and where they will be operating. The high mobility of tanks and motorized infantry will also permit them to carry out a swift maneuver in any direction if they are supplied with suitable itineraries (marshrut dvizheniya).

Thus, under modern conditions, the concentration of the efforts of the troops is determined, not by the creation of powerful groupings and great densities of the forces and weapons of the ground troops, but, primarily, by the quantity and power of the nuclear weapons which can be used in one direction or another and for the performance of the most important tasks.

Finally, in speaking of the selection of the main strike direction, it should be noted that under modern conditions this term is beginning to acquire a highly conditional connotation. It must be realized that in view of the threats of nuclear strikes, the defending enemy will not allow large concentrations of troops in any one definite direction. By maneuvering the strikes of his nuclear weapons, dispersed throughout the entire defense zone, he can quickly intensify the efforts of troops in any direction where the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

situation demands it. For these reasons, powerful strike groupings will not be built up in the advancing troops as previously and, indeed, perhaps the necessity for them will disappear since the advance will probably be conducted by small troop groupings in separate and most advantageous directions. In addition, it must be considered that fronts will not now obtain the quantity of troops which they had in the past war. The tasks of operations and of the war will be resolved primarily by nuclear weapons, while the infantry and tanks will be used for the destruction of the remnants of the enemy and for the consolidation of occupied territory.

In connection with all that has been said, the conclusion suggests itself that, under modern conditions, it is more correct to speak not of the selection of the main strike direction but of the determination of the main tasks of an operation toward whose fulfillment the basic efforts of the means of nuclear assault and of the troops should be directed.

Thus, the requirements established by us for the selection of the main strike direction need serious correction. If there is a sufficient quantity of nuclear weapons, these must be used immediately for the destruction of the basic enemy grouping and the main strike by the ground troops must be delivered in this direction; if these means are not available it will be necessary to resort to cunning and deception, to seek out the enemy's weak spots, to maneuver, and to achieve victory by a more difficult and dangerous path. It must be borne in mind that the sensitivity of the troops to strikes along their flanks and rear is not weakened in the least by the fact that they have been armed with nuclear weapons. Therefore, the delivery of a strike against the enemy's weakest spot retains its full significance in all cases when, for some reason, it is not possible to employ nuclear weapons, when they are insufficient or when they are completely lacking. This is especially applicable to the operations of the troops in the depth of the enemy's defense.

The quantity of strikes in a front. As a rule, during operations in World War II, a front, in addition to the main strike, also delivered

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

one and, less frequently, two auxiliary strikes. An army practically always delivered one strike. This system for the delivery of strikes by a front and an army is employed, without any changes, in the organization of modern operations. Attempts to deliver a large number of strikes and to disperse the striking groupings somewhat are often seen by us as a dissipation of the efforts of the troops.

It seems to us that, in this question, too, a mechanical transfer of past experience to modern conditions is taking place. When there were no nuclear weapons or missiles, the front was indeed unable to deliver more than two or three strikes since it did not have either the forces or the weapons to do this. Much time was required to maneuver forces and weapons from one direction to another and fire maneuver was limited.

Modern nuclear/missile weapons permit the execution of a maneuver with nuclear strikes along the entire zone of a front and can ensure the destruction of the enemy by advancing troops at any point of his defense. It is therefore entirely possible that, during operations by motorized rifle and tank divisions in separate directions, a front may deliver three, four, and five strikes, coordinated by general concept and directed at the attainment of the goals assigned to the operation. A sufficient quantity of forces and weapons must be assigned to each direction to ensure the fulfillment of the task which has been allotted and to make dense operational and combat formation unnecessary. / Sentence missing /---------- Between adjacent strike groupings and also between separate large units there can be considerable gaps.

Under modern conditions, it is not important how many groupings have been established for an offensive in a front, although this, too, has considerable significance but, primarily, how their advance is organized, where it is directed to, which main tasks are carried out with the aid of nuclear weapons, and how the infantry and tanks are to exploit the results of nuclear strikes in order to advance at maximum speeds. The dispersion of forces

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and weapons throughout the entire zone of the front does not by any means indicate that the efforts of the troops are being dissipated. One must look at the essence of the situation and not at the outward form. And the essence is that, irrespective of the disposition of forces and weapons, the basic efforts of the troops of the front should be directed towards the solution of the main task--the destruction of the enemy's basic grouping. Here it is appropriate to recall the well-known saying "go separately but fight together." Nuclear/missile weapons allow this maxim to be fully realized.

The operational formation of the troops of a front in an offensive operation. In the resolution of this question, too, the changes essential in any comparison with the last period of World War II have not taken place. Powerful, strike groupings of troops, of low mobility, continue to be set up for an offensive. In the process, two echelons are created in a front as a rule and, in addition, a general reserve of several divisions is set up. If one takes into account that armies, divisions, and even regiments can also advance in a two-echelon formation, it turns out that nearly 75 percent of all the forces and weapons of the front will be located in the second echelons and the reserves.

Such a situation was normal and even necessary during the period of World War II since, at that time, commanders and commanding officers had no means for performing subsequent tasks or for the development of the offensive in depth, other than the second echelons and reserves. Furthermore, there were no effective long-range means of destruction which could have threatened the second echelons which, until their committment to combat or engagement, hardly ever suffered any serious losses.

Things are different in modern operations. The availability of missile weapons makes it possible to provide effective support to the troops with nuclear strikes throughout the entire depth of an operation and to support the development of the offensive in any

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

direction. The commanders of the armies and troops of the front can now influence the course of the operation not so much through the second echelons, which will be located at a great distance from the first echelons, as through strikes by nuclear weapons and by strong, highly-mobile and maneuvering reserves.

Front and army reserves must be echeloned in depth, must move in a dispersed fashion and must be used to develop the success of the operation, to relieve divisions which have suffered great losses and have lost their combat efficiency, to repel enemy counterstrike, , and to carry out other unforseen tasks which may appear in the course of the operation. Here one should remember that,in connection with possible sharp changes in the situation, the replacement of some divisions by others during the course of an operation will take place repeatedly and fairly frequently.

For this reason, and also because of the complexity of control in modern operations, separate large units and units located in the reserve can be directed beforehand to fulfil definite tasks as is now done for second echelons.

Under modern conditions the operational formation of a front or an army should be no less flexible than the combat formation of a regiment or a division, in accordance, of course, with their sizes. This suggests the conclusion that the many-echeloned operational troop formation which we use in offensive operations does not correspond to the changed conditions in the conduct of combat operations and requires serious review. One may agree that, with modern means of destruction, the two-echeloned formation in a regiment and in a division can be to some extent justified. As regards an army and, even more so, a front, however, the creation of second echelons in the old concept is not necessary. Their tasks can be performed most effectively by the more mobile reserves, which are maneuverable, and echeloned in depth.

Coordination (Vzaimodeystviye). The basic principle of coordination -- the synchronization of the efforts of troops in the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

carrying out of tasks concerned with the aim, place and time of an operation-- retains all its significance under modern conditions, but one should include in it another constituent produced by the new means of armed combat and by the changed nature of combat operations.

In each stage of an operation and during the fulfillment of any task, Soviet military art requires that coordination be organized in the interests of those large units and formations which play the main role in the performance of the tasks allotted and in the attainment of the goals of the operation. Previously, in offensive operations by ground troops, coordination was organized most frequently in the interests of the infantry and tanks because they represented the principal means of performing the allotted tasks. Today, this question must be resolved in a different manner, since the principle means of combat are nuclear/missile weapons, and it seems that it will be necessary to arrange coordination in support of the operations of missile large units and units.

It appears to us that support for the fulfillment of the two main tasks should form the basis of coordination in modern operations. The first task is the destruction of the enemy's means of nuclear assault; the troops will be faced with this from the beginning to the end of an offensive operation and also, during the operational lull (if there is one) while the troops are preparing for a new operation. The second task is the timely exploitation by the advancing troops of the results achieved by nuclear strikes, with the aim of completely destroying the enemy. Both these tasks are of paramount significance. The success of an operation depends upon their fulfillment.

In considering the first task, it should be noted that the enemy's means of nuclear assault, located not only in the zone of (a front's) advance but also in the zones of adjacent fronts and beyond their limits, represent a great danger to the front. The destruction of these means must therefore be carried out not only by forces of one front but also by those of adjacent fronts and armies; those enemy means which are out of range must be

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

destroyed by the strategic missile troops / a few lines missing / ---- ------ With the help of nuclear weapons large losses can be inflicted on opposing enemy groupings and their combat efficiency can be seriously reduced, but it will not always be possible to destroy them completely or to force them to capitulate. First among those who are in a position to perform this task are the ground troops - the infantry and the tanks. It is they who must exploit the results of nuclear strikes and complete the final destruction of the enemy. Therefore, during the arrangement of coordination in the delivery of nuclear strikes, there must be agreement on the place and time of the subsequent operations of the infantry and tanks with a view to the maximum utilization of their combat capabilities. Nuclear weapons must clear the way for the infantry and tanks, while the latter, taking advantage of the results of nuclear strikes, must push forward with determination, break the organized resistance of the remaining enemy forces, and consolidate the territory which has been occupied.

The remaining questions of coordination in an offensive operation must be resolved with regard to and in accordance with the accomplishment of the two basic tasks mentioned above.

In organizing coordination in modern operations, it is also very important to ensure the maximum viability of our own means of nuclear assault, their timely preparation for an operation and an agreed place and time for the delivery of nuclear strikes.

Methods of conducting offensive operations. The experience of many exercises shows that even in the first operations of the initial period of a war, we often envisage the timely concentration of troops in the attack positions, their deployment in combat formation, the carrying out of artillery and air preparation and a subsequent transition to the offensive. Generally, such an opportunity is not to be excluded in a period of threat (ugrozhayemyy period), if there is one, but this will not be typical for troop activities in operations during the initial period of a war, which are conducted with the mass use of nuclear weapons.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

As we have already said, the first and decisive act of a future war will be the mutual delivery of mass nuclear strikes by both sides, with the aim of destroying the means of nuclear assault of the enemy, the disorganization of his deep rear, the destruction of his most important military-economic and administrative-political centers, the creation of complete chaos in the country, the undermining of popular morale and the destruction of the basic groupings of armed forces.. Therefore, the first offensive operations will most probably be initiated by those troops who have escaped the enemy's nuclear strikes, in those directions which have already been determined for them in peacetime.

The transition to the offensive of these troops will not be preceded by artillery or air preparation. These methods of using artillery and aircraft in combat, which were highly recommended during World War II, have already lost their former significance and do not correspond to the modern capabilities of the Armed Forces. It is not these means but nuclear weapons which will now determine the content of the fire preparation for an offensive.

The first offensive operations in a future war will develop simultaneously with or after strikes by the missile troops which will prepare the shortest and most advantageous ways (napravleniye) for the advancing troops to attain the goals assigned to the operation. Only during the course of the offensive in the depth of the enemy's defense can the means of close combat - aircraft, artillery, and small arms - find combat application. The nuclear offensive has replaced the former artillery and air offensive and it will determine the success of the operations.

The main tasks of the advancing troops in the first operations will be, while exploiting the results of nuclear/missile strikes to the full, to complete the destruction of the remaining enemy groupings, to capture the areas where his basic means of armed combat are based, and to paralyze any effort by the enemy to put himself in order or to offer organized resistance. Time and, consequently, the speed of the advance will play a decisive role

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

in the fulfillment of this task. He who first seizes the initiative and who acts more quickly and more decisively will be in the better position. For this, according to our estimates, troops should move forward at an average speed of not less than 100 kilometers in every 24 hours. Such speeds can only be guaranteed by troops who are highly trained, mobile, and well provided with a variety of equipment, who are capable of restoring roads and bridges in a limited time and of crossing water obstacles quickly, of operating in zones contaminated by radioactivity, in areas where there are fires and obstructions, and under other difficult conditions. The surprise factor and the destructive power of nuclear/missile strikes make it impossible for the enemy to set up organized defense over any significant area of the front near the border or in the depth of his country. Large gaps and unoccupied sectors of terrain are inevitable in his troop grouping and in his defense system. Even if the enemy were successful in creating such a defense in several directions, it would be completely disrupted by mass nuclear/missile strikes. Under these conditions there is no need to conduct a methodical advance in combat order. Most probably the basic method of troop operations will be an advance by highly maneuverable columns of tanks and of infantry on armored carriers. These columns must move ahead swiftly, going around or overcoming obstacles, barriers, contaminated sectors of the terrain and other obstructions. With tank fire they must quickly destroy the enemy groupings which attempt to offer resistance, and, in cases where this cannot be done, they must search out places which are not occupied by the enemy, break through them and continue to move forward without pause, allocating part of their strength to deliver strikes against the flanks and rear of the defending enemy grouping or leaving large covering detachments (deployed) against it. Sometimes the accomplishment of this task will be left to the echelons and reserves which are following. In order to avoid the loss of high speeds of advance, one should not get involved in prolonged battles, even if the enemy is successful at some point in recapturing the basic directions in the zone of a front or of an army and in organizing their defense. In such a situation, it is better to go round the enemy and to transfer the efforts of the troops immediately to other directions or to withdraw one's own troops to a safe

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

distance and to deliver repeated nuclear strikes on the consolidated enemy grouping, exploiting their results to continue the advance.

Aggressive and decisive operations by airborne troops, who are dropped in the enemy's rear and across the route along which he is moving and, especially, while troops are negotiating zones which are contaminated by radioactivity or wide water barriers, are acquiring great scope and increasing significance in offensive operations. / Several words missing /----------high speeds of movement of the advancing troops and their performance of tasks aimed at the final destruction of the enemy.

In the course of offensive operations, the most varied types of combat operations are possible: in some directions troops will move forward swiftly, meeting no serious enemy resistance, or will perform a turning maneuver; in others large head-on collisions may develop or the troops may be compelled to conduct defensive operations, to contain an offensive by superior enemy forces and to repulse strikes by his airborne troops; in still other directions, the troops may overcome the enemy's defense or may withdraw in order to make possible the delivery of repeated nuclear/missile strikes on the enemy. Very frequently, troops will have to negotiate contaminated sectors of terrain with high levels of radiation, obstructions, and other obstacles which are created by nuclear strikes. As a result of such operations, the front line, as it used to be understood, will disappear. Front and army engagements will develop across vast areas along the front and in depth and will become separate centers, areas and zones of combat operations of the most varied scope and nature. The driving of deep mutual wedges (vzaimnoye vklineniye) by the troops will become a general phenomenon. Our troops may find themselves deep in the enemy's rear and his troops will conduct aggressive combat operations in the rear of ours.

Although the troops will have to conduct such a variety of combat operations in the course of an offensive, the basis of all

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

these operations must be wide maneuver, founded on the use of a mobile/combat (pokhodnoboyevoy) order, i. e., coupling a swift forward movement in small columns with operations in combat formations when this is demanded by the situation. When nuclear weapons are being used, such a method of operations can provide the best assurance of a high rate of advance and of the performance of tactical and operational tasks in significantly shorter periods of time than was possible with earlier means of armed combat. As a result of this, the duration of offensive operations can be greatly shortened despite their increased depth.

This, in general terms, is how we see the methods of conducting an offensive in the operations during the initial period of a war.

We have very briefly surveyed separate questions of offensive operations in order to show the disparity which exists in a number of cases between the methods of troop operations in modern operations and the combat capabilities of the new means of armed combat. . Such disparity can be found in a number of other questions of military art.

Of course, our reasoning cannot pretend to represent any degree of exhaustive argument. The questions which we have touched upon, like many other questions of modern military art, require profound and complete study and research, and practical testing on "battle" training grounds. A fraction of this study is represented by the attempt of this article to provide a critical analysis of the nature of the operation of one of the most important laws of development in military art - the law of the interconnection and interdependence of means and weapons of armed combat - and to show the fulfillment of the requirements of this law in our resolution of the questions of the preparation and conduct of modern operations.

Some Problems in the Preparation of the Rear Area for Support of the Armed Forces in the Initial Period of a War

by Colonel-General F. Malykhin

Fundamental changes in the nature of a future war require a basically new approach to the resolution of a series of highly important problems in the materiel-technical support of armed combat.

We have in mind, first of all, the problems of rear area support of all types of Armed Forces when missile troops have the leading role in the theaters of military operations and simultaneously, the fulfilment of missions for the protection of the zone of the interior and the groupings of the Armed Forces in the depth, from enemy strikes with weapons of mass destruction. In brief, we are discussing the necessity of developing special theoretical postulates concerning the utilization of those tremendous forces and means which will be made available by the State for the comprehensive rear area support of the Armed Forces at the beginning of a war.

In none of the previous wars was this problem so keen and urgent. Even during the period of the Second World War the attention of military leaders with respect to the rear area support of the Armed Forces was directed mainly at the delivery of allotted materiel-technical supplies to the fronts and to their proper utilization in the theaters of military operations. Moreover, the delivery of a significant part of the supplies to the consumers, i.e., to the distribution stations of the front, was carried out by elements of the national economy. Those supplies which were delivered to the central supply elements, could be delivered to the fronts in a planned manner by using the regularly operating transportation network of the country. The disruption of delivery plans by the enemy took place primarily in the rear areas of the front and in zones directly adjacent to them.

Completely different conditions for rear area support of the Armed Forces will prevail in modern warfare.

In delineating the conditions of work in the rear area of the Armed Forces, it is necessary to bear the following factors in mind above all:

- the necessity of simultaneous support of operations of fronts

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

in different theaters of military operations and of those groupings of the Armed Forces which are carrying out combat missions in the deep rear;

- the provision of reliable transportation networks for the rear area and for the front, and between theaters of military operations, for supplying fronts with everything necessary and for carrying out strategic and large operational regroupings;

- the difficulties of ensuring protection of the rear area of the Armed Forces from the means of mass destruction over the entire territory of the country.

In modern conditions the combat readiness of the Armed Forces, as never before, depends upon the timely preparation and stability of rear area support. For this reason the theoretical development and serious scientific investigation of problems of the rear area support of the Armed Forces at its present stage must be viewed as the most important tasks.

The modern rear services of the Armed Forces represent a huge organism which must be arranged in such a way as to support continuously, with minimum losses, the combat activity of fronts, the Antiaircraft Defense Troops of the Country; and reserves of the General Headquarters of the Supreme High Command in precise conformity with their missions and the situation.

By the rear services of the Armed Forces, in our opinion, one should understand both the forces and equipment included organizationally in the complement of the Armed Forces and those attached by the State to the jurisdiction of a military command for overall materiel, technical, and medical support and for the servicing of missile and ground troops, troops of antiaircraft defense of the country, and the air forces and the navy.

Depending upon the nature of the missions being fulfilled, conditions of work [1 or 2 words missing] and the organizational order, the forces and means of the rear area of the Armed Forces [are divided into the following] elements: troop, operational, and central.

[The troop element] is composed of rear services units and subunits, [2 or 3 words missing] materiel-technical supplies and property [2 or 3 words missing] of supporting the combat activity of large units [and units].

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The operational element of the rear is composed organizationally of special organs of control of rear services large units, units, and installations of fronts, armies, fleets (flotillas), and PVO districts. It is designated for organization and implementation of measures for materiel, technical, and medical support of troops, preparation, restoration, and utilization of transportation routes, and other work in support of the combat activity of troops.

The central element of the rear services includes a large number of various large units, units, and installations, bases, depots, arsenals, repair plants, and other production enterprises of the Ministry of Defense designated for the rear services support of all the Armed Forces of the country (their various types), and at the same time constituting the reserve of the Supreme High Command and Commanders-in-chief of the types of Armed Forces.

The central organs of the rear services of the Armed Forces utilize the transportation network of the national economy in accordance with the full needs of the Armed Forces, and also the forces and means of State reserves and the mobilization potential of industry prepared during peacetime and assigned to their jurisdiction by special government decrees.

/2 or 3 words missing/ in the preparation of the rear services of the Armed Forces for warfare is extremely large. In this article we shall endeavour to set forth our point of view only on the most important problems, having, in our opinion, primary significance for fulfilling practical missions of preparation of the rear services for the support of the Armed Forces in the initial period of a war.

In these problems we refer first of all to the changing role of stocks of materiel, determination of their size and principles of their echelonment, the preparation of communication routes, and means of transport, and problems of developing new forms of control of the rear services of the Armed Forces.

* * *

With the growth in size of armies, adoption of new, more sophisticated means of armed combat, increase in offensive tempos, and the intensity of defensive engagements, the materiel requirements of the troops increase correspondingly. During the First World War the Russian Army expended about one million tons of ammunition and a total of several tens of thousands of tons of fuel. During the period of the Second

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

World War the total expenditure of ammunition by the Soviet Armed Forces comprised about 8 million tons, and fuel - more than 13 million tons.

The materiel expenditures of the Armed Forces in a future war apparently will increase even more. The high level of technical outfitting of the Armed Forces has caused a significant increase in the estimated units of supply expressed in weight. Thus, the weight of a unit of fire of a modern front (without aviation) currently amounts to 18.5 thousand tons, and fuel servicing exceeds 22 thousand tons. Calculations indicate that for 8 to 10 calendar days of an offensive operation, developing speeds of 80 to 100 km in a calendar day, and for the period of its preparation, the troops of a front may expend upwards of 240 thousand tons of fuel and about 120 thousand tons of various ammunition. To this should be added the probability of increased combat losses from weapons of mass destruction. It follows that the quantitative growth of materiel expenditures conforms to an objective law.

Along with the quantitative changes in modern conditions, as a result of equipping the Armed Forces with new types of arms, great qualitative changes in materiel requirements have taken place. A future war will be a nuclear/missile war, in which the decisive type of Armed Forces will be missile troops of strategic designation, and the basis of the firepower of each of the types of Armed Forces will be their missile weapons. In connection with this, the supply of troops with missiles, missile fuel, and other special materiel for missile troops acquires primary significance. The need, however, for conventional types of ammunition, especially for tube artillery and aircraft bombs, is decreasing significantly at the present time. Speaking of the decrease of the needs of the troops for these types of ammunition, we are basing it on the fact that fire preparation and the support of operations during broad use of nuclear/missile weapons will undergo great changes. An offensive will be carried out at great speeds with broad utilization of nuclear weapons. Nuclear/missile weapons will also form the basis of defensive fire.

No less serious qualitative changes have also taken place in the fuel requirements of the Armed Forces. The proportion of aviation fuel in the total expenditure of fuel has significantly decreased, with a simultaneous colossal growth in the fuel requirement of ground equipment. The supply of troops with missile fuel has acquired the greatest significance.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Serious qualitative changes in the requirements of the Armed Forces also arise from their increased technical outfitting.

In a future war, much very complex equipment will be used. For this reason one of the main missions of the rear services is the uninterrupted supply of the Armed Forces with technical equipment for the use, repair, and servicing of nuclear, missile, and radioelectronic equipment, tanks, motor vehicles, and other materiel.

While, during the Second World War, this equipment comprised altogether only 8 to 10 percent of the weight of expended ammunition, fuel, and rations, its present proportion has grown to 20 to 25 percent.

The preceding statements permit the conclusion that under modern conditions the basic types of materiel supplies for support of the Armed Forces may be considered to be: missiles and assorted nuclear ammunition, missile fuel, artillery ammunition, fuel for ground equipment and aircraft, technical equipment, and rations.

The uninterrupted support of troops with these types of materiel supplies as the first priority in modern conditions is one of the chief factors in their high combat readiness, and depends upon the status of the supplies and accumulated stocks in case of a war.

In our time the significance of materiel supplies has grown immeasurably.

The role and size of stocks depends first of all on the volume of materiel expenditures, the urgency with which needs may arise, and the capacity of the transportation system to guarantee uninterrupted delivery of freight from the place of production to the consumers. Under modern conditions, with increased requirements for materiel supplies and the great vulnerability of the routes of communication and transportation, guaranteeing the uninterrupted flow of goods will be extremely difficult, and in certain instances altogether impossible. Namely for this reason, stocks of materiel supplies created in advance in all elements of the Armed Forces will, as never before, be essential for guaranteeing the constant combat readiness of troops. This is especially important for guaranteeing the strategic deployment of the Armed Forces and conduct of operations during the initial period of a war, when industry will only be converting to military production, the transportation network will be occupied mainly with movements for the concentration of troops, and in a number of areas may be disrupted by the first massive nuclear/missile strikes of the enemy.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

Arguments are now in process concerning the size and order of echelonment of stocks created in peacetime. Certain comrades advise maximum reduction of stocks with the aim of supposedly easing the burden of troops further. We are against such an approach to the resolution of this important problem.

The correct determination of the essential scale of materiel stocks accumulated in advance has been a subject of special concern to governments, general staffs, and the rear services elements of their armed forces throughout the course of the entire history of warfare.

In our opinion, during the development of plans for the rear services support of the Armed Forces in the initial period of a modern war, careful consideration should be given such factors as:

- the strategic goals facing the armed forces along strategic axes (theaters of military operations);

- the total volume of materiel requirements [1 or 2 words missing] of the Armed Forces;

- the probable period of conversion of current production to military needs;

- the degree of preparation of the transportation system of the country for uninterrupted work in carrying out planned movements of troops and bringing up of materiel supplies under conditions of the initial nuclear/missile strikes;

- the economic potentialities of the country (of the combined countries), and the state of combat equipment development (the possibility of rapid obsolescence of accumulated ammunition, technical, and other supplies).

On the basis of the experience of the last war, and after consideration of the postwar changes of the factors indicated above, we assume that, in preparation for war, it is essential to create stocks of materiel in advance directly within the troops, with the armies and fronts planned for deployment, and under the jurisdiction of the central organ of the rear services of the Armed Forces. We consider the following to be the optimum sizes of these stocks applicable to the western axis:

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

- general stocks of deployed fronts (mobile - troop, army, and front) calculated on the monthly requirement of the troops;

- supplies of the central organ of the rear services, calculated on the three-month requirements of all the Armed Forces of the country, taking mobilization buildup into account.

When determining the size of the stocks, which are eligible for prior creation and regular maintenance within the troops, in army and district depots (depots of groups of troops), we proceed from the fact that in the first 20 to 25 calendar days after the initiation of war, the main types of transport will be converted primarily to operational movements of troops for supporting strategic concentration and deployment of future fronts.[1] On overland communication routes a large number of barriers and centers of persistent contamination will be formed. A portion of the peacetime stocks will be subject to contamination or will be annihilated by the initial nuclear strikes of the enemy. For this reason the delivery of materiel supplies during the course of the first and even partly during the second offensive operation of the front will be extremely difficult. In volume it apparently will not exceed 25 to 30 percent of the monthly requirements of the troops, which might cover only the combat losses and form some reserve for supporting the combat effectiveness of troops until the moment of establishment of a system of uninterrupted supply of the operating army for the delivery of everything necessary from the depots and bases of the center.

In the determination of the size of stocks, which it is feasible to accumulate in advance and maintain at central bases, taking into account all the above-listed factors, we took as a base the time necessary for the buildup of the mobilization potential and for the conversion of industry to war production.

As is known, three months were required during the last world war for the conversion of industry to the military needs of our country, during the course of which bases for production of combat equipment and various military materiel were created in interior areas. Already

---

1. The period of the most intensive operational movements on railroads of the USSR at the beginning of the Second World War lasted for about a month. During this time the volume of supply movements was very low. During the first 10 days of mobilization it made up altogether only 10 percent of the total volume of military railway movements.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

in October-November 1941, our Armed Forces began to receive regularly everything necessary for combat and life from current production. It is this very period that we are taking into account, proposing minimum quantities of supplies at the center for supporting the Armed Forces at the beginning of a future war.

We may hear objections that the last war was started with extremely disadvantageous conditions of enemy superiority; the organization of military production in the summer of 1941 was combined with the evacuation of a large number of enterprises to the East; in addition to this, our supply organs did not have sufficient practical experience in the fulfilment of these complex missions, etc.

All this, undoubtedly, should be considered. However, it is impossible to overlook the new difficulties connected with the enemy capability of carrying out nuclear/missile strikes against important economic centers over the entire territory of the country. For this reason we take into consideration the potential possibility of annihilation, or heavy destruction, of a number of enterprises and bases and, consequently, also, a substantial decrease in mobilization potential and State reserves in the first days of a war.

Under modern conditions, with the great vulnerability of the lines of communication, the correct determination of the echelonment of stocks of materiel supplies will have exceptionally important significance. The accepted order of echelonment and location of stocks has direct influence on the creation of conditions of autonomy and independence of troop operations and on the viability of the system of rear area support during widespread utilization of weapons of mass destruction.

We consider that for a deploying front, as regards a western axis, stocks should be echeloned in the following order:

- with the troops (in regimental and divisional depots) - mobile stocks on motor vehicles in amounts required by the troops for three or four calendar days of medium intensity combat;

- in army depots - similarly mobile stocks for two calendar days;

- in front depots (of military districts, groups of troops) for 20-25 calendar days requirements of the grouping being supported.

A modern division is a highly mobile, fully mechanized large unit, capable of engaging in combat under complex conditions, along an

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

independent axis, as a landing force, etc. For this reason it is very important to create definite conditions of autonomy for the division, opportunities to conduct combat while cut off from bases of supply, with broken communication lines, and in other instances of complex combat situations. In the interests of easing the burden of the division, during the last years its rear services have been significantly decreased and stocks of materiel supplies have been substantially lowered. Further decrease of stocks in the division, in our opinion, is already impossible. As long as the basic means of transport continues to be land transportation, based on highly vulnerable routes of communication, the lowering of the mobile stocks below the level of three to four calendar day requirements of the division will inevitably harm the combat effectiveness of the troops. This pertains especially to fuel, without which modern, fully mechanized troops may become immobile targets for the enemy.

It is known that the expenditure of fuel during a calendar day when the speed of the offensive is 80 to 100 km may amount to: diesel fuel for heavy tanks, 1.3 fuelings, and for medium tanks, 0.7 fuelings; aviation gasoline for armored carriers, 0.7 fuelings, motor vehicle gasoline for combat and transport vehicles, 0.45 fuelings. If with such expenditure the divisional supply of diesel fuel drops to two fuelings, and aviation and other gasoline to 1.25 fuelings, then in case of disruption of transport, the troops will not be able to continue the fulfilment of their combat missions after one and a half to two calendar days.

For this reason we categorically object to those who, viewing the idea of easing the burden of the troops as a goal in itself, recommend lowering the fuel stocks in a division to one and a half to two calender day requirements.

We consider that the very minimum mobile stocks of fuel in a division must be: motor vehicle gasoline - 1.4 fuelings, diesel fuel - 2.5 fuelings.[1]

The combined-arms and tank armies, under modern conditions, form the basis of both operational internal and operational interfrontal maneuver. For this reason, it is extremely essential to have at the

---

1. All fuel calculations were carried out on the basis that motor vehicles have a cruising range of 500 km, and for tanks, taking into consideration the fuel in all fuel tanks making up the fuel system of tanks.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

disposal of the army commander at least minimal reserves of materiel supplies for operational influence on sharp and unexpected changes in the situation. Such a reserve is proposed by us for a combined-arms army on the scale of troop requirements for two calendar days, and for a tank army - for one calendar day.

In connection with such a lowering of stocks with the troops and at mobile army bases, as well as in connection with the significant decrease of other forces and materiel of these elements of the rear services, there has appeared a necessity to alter the echelonment of stocks of a front. In the interests of bringing these stocks nearer to the troops supported, we consider that up to 60 percent of them should be maintained in forward bases of the front, which, with great strain on the communication lines, can move their sections forward. The remaining 40 percent of the stocks of the front may be kept in rear area bases of the front for the regular replenishing of forward bases, for deliveries by air transport to armies, and for the direct support of troops carrying out missions in the depth of the rear area.

Such a system of stocks echelonment in the zone of operations of the front, in our opinion, more readily satisfies the requirements of uninterrupted support of troops under the complex conditions of modern operations.

Certain comrades consider that in order to avoid unnecessary transshipment, bases should not be formed in the deep rear area of a front. Thus, for example, it is proposed to have one front missile-technical base with two sections, which must deploy in an area along a 200 to 250 km front and 100 to 150 km in depth. Such a scheme, seemingly very simple at first glance, may become, in actual conditions, very complex, and will not guarantee the fulfilment of assigned missions. It does not satisfy the requirements of maximum dispersion, stability of supply during the sudden appearance of barriers on lines of communication, and hinders support of missile large units deployed in the depth of the rear area.

In view of the great vulnerability of rear area lines of communication, remoteness of theaters of military operations, and the long-range ability of modern means of attack, the problem of correct echelonment of stocks of the central organ of the rear services of the Armed Forces has arisen sharply at the present time.

The investigation of this problem leads to the conclusion that

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

in our time the stocks of the center should be maintained in two echelons: in the border zone and in the zone of interior. By the border zone, we mean the groups of our troops located on the territory of countries of the Peoples' Democracies, the territory of Warsaw Pact countries contiguous with our borders, and, for military districts, the border areas of the USSR.

The moving out of bases of the center on the Western axis beyond our borders, with the moving of stocks nearer to troops supported, will permit us in initial operations to avoid dependence on vulnerable railroad meeting points of Soviet and European gauges.

During the echelonment of stocks in border areas, their distribution along the axes of probable troop operations must also be provided for, taking into consideration requirements of groupings of the Armed Forces for materiel stocks along a particular axis.

Altogether in the bases of the center in the border zone, there should be 50 to 60 percent of the total volume of stocks of the center which are accumulated ahead of time. It is advisable to create the remaining portion (50 to 40 percent) in the zone of interior, located in scattered places sheltered from nuclear/missile strikes of the enemy. These stocks will be utilized to support the full mobilization of the Armed Forces, troop operations of the antiaircraft defense of the country, missile troops of strategic designation, and other groupings fulfilling combat missions in the zone of interior.

During the distribution of stocks created ahead of time, special attention should be given to their preservation during enemy attack with weapons of mass destruction. The preservation of troop and army stocks is assured chiefly by the mobility of bases and depots. Insofar as the stocks of the front and bases of the center are concerned, in the interests of great security, they should be located at an appropriate distance from probable targets of nuclear strikes, in sheltered places and carefully concealed. Unfortunately, at the present time this vital principal is a long way from being observed everywhere.

It appears to us, that we should not be carried away with the creation of large bases, the sheltering and concealment of which would require huge resources. It is considerably more advantageous to create smaller bases, to spread them over a larger territory, and place them at a distance from possible targets of enemy nuclear/missile strikes.

The stocks of materiel supplies of the center need not be located

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

only in bases under the jurisdiction of the military command. A portion of these stocks may also be located in bases of State materiel reserves, but which are earmarked even in peacetime for support of troops in the initial period of a war. The military command must take part in the determination of the size and points for locating these stocks. The stocks of the center must be constantly kept prepared for movement, and ramps and approach routes must be prepared in advance on the various fronts for all types of transport.

Under modern conditions large shipments of materiel supplies, from the central bases and depots, can be accomplished by air transport, so it is very important to have a prepared network of airfields in the area of these bases, approaches to them, transportation for bringing up freight to the airfields, and also a labor force with loading-unloading equipment.

Such preparation has special significance for missile bases, dumps of missile fuels, and special articles (izdeliye), belonging to the armament of missile troops. The most advantageous way to move materiel supplies of this type will be over great distances from the deep rear directly to the points of their utilization.

Thus, the most important problem of supporting troops in the initial period of a war and during the strategic deployment of the Armed Forces is the accumulation of the required stocks of materiel supplies ahead of time, their proper location and echelonment, and their reliable protection from enemy strikes. The timely and purposeful resolution of this problem will form the most important materiel basis for armed conflict in the initial period of a future war. This will also reflect, to a significant degree, upon the successes of our Armed Forces during the subsequent course of the war.

* * *

The conditions for conduct of armed combat in a future war bring up a series of new, highly important problems in the realm of preparation of communication lines and means of transport.

In the interests of assuring the required viability of the rail and motor vehicle roads which form the basis of the transportation system in internal areas and in the prefrontal zone, it is essential, still in peacetime, to carry out a number of important measures.

Among these measures are the following, above all:

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

- the development of a network of roads on the required strategic and operational axes;

- the construction of deep and local bypasses of large junctions, administrative-political, and industrial-economic centers;

- the preparation of alternate crossings over water obstacles;

- the preparation of modern types of transport.

In the postwar period our country has significantly broadened the program of construction of lines of communication.

A large measure of capital investment is directed toward the fulfilment of these missions. With the goal of looking after the interests of the Armed Forces, the appropriate elements of the Ministry of Defense must very vigorously place before the planning elements of the national economy the missions for ensuring dependable communication lines for the vitally important strategic axes which run through economically less-developed areas of the territory of the country. These very important measures must be given foremost attention by State planning organs, as well as by organs of the Ministry of Defense.

We consider one of the most important problems in the preparation of the rear services of the Armed Forces for war to be the long-range development of a network of communication lines in precise conformity with strategic plans being developed for the conduct of armed combat.

Under conditions of a modern nuclear/missile war, when the stability of the operation of networks of communication lines in internal areas of the country becomes the most important factor in the maneuvering of armed forces and in ensuring the fulfilment of strategic missions by them, views on the preparation of communication routes for operation in wartime change radically. At present the mission of constructing deep and local (depending upon the importance of the target) bypasses of centers of communication routes, large stations, transshipping, and other narrow points and sectors, as well as bypasses of large administrative and industrial centers, should be pushed to the fore. Only by having such bypasses prepared ahead of time is it possible to count on assuring uninterrupted operation of transport by rapid transfer of the flow of trains and motor vehicle march columns to alternate routes or to adjacent axes.

It is no less important to carry out preparatory measures ahead of time, ensuring uninterrupted military movements across large water

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

barriers. In our opinion, the resolution of this problem may be achieved by implementation of a complex of various measures. Of these, we must first of all mention the construction of main alternate bridges, the cutting and filling of roadbeds, and also in certain instances, the laying of load-bearing surfaces on the approaches to points where temporary alternate crossings are being erected. To shorten the periods for reestablishment of traffic in cases of destruction of bridges by the enemy, it is essential, already at the present time, to develop broadly the procurement and accumulation of stocks of materials for erecting floating rail and motor vehicle bridges and ferry crossings. In addition, it is essential to have such materials directly under the control of the Ministry of Defense for concentration along the most important operational axes, as well as under the jurisdiction of the Ministry of Transport Construction for maintenance of rear area roads where barriers are most likely to occur. In the fulfilment of this mission, a significant reserve for the decrease of capital investment may be the adaptation of floating river equipment for the erection of temporary floating rail and motor vehicle bridges and ferry crossings. In terms of capacity of the river tug fleet and freight-carrying capacity of the towed fleet in river basins, the Soviet Union at the present time occupies first place in Europe and second in the world. This fleet is growing rapidly. During the period from 1951 to 1958 alone, the freight-carrying capacity of the self-propelled and towed river fleets increased by more than 3.5 million tons.

In the makeup of the river fleet there is a large number of barge-lighters with a freight-carrying capacity of 300-2000 tons, open double-bottomed metal barges with freight-carrying capacities of 1800-3000 tons, and other cargo vessels, entirely suitable for rapid erection of floating bridges of any length. For the rational utilization of this reserve and appropriate preparation of vessels, it appears essential to develop their fixed tonnage for series production and to achieve the introduction of certain design changes, especially in the superstructure.

Closely related to the resolution of the problems listed is the need to organize vigorous protection of major transport installations from the means of enemy attack (allotment of antiaircraft defense means). It is extremely essential at the initiation of military operations to screen basic installations (large centers on main lines of strategic designation, rail meeting points of Soviet and West European gauges, large bridges) reliably with antimissile and antiaircraft weapons. It appears to us that this problem must be worked out beforehand by the joint efforts of elements of PVO Troops of the Country and the rear services

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

of the Armed Forces.

In the resolution of problems concerning the stability of the system of the rear services support of the Armed Forces and the strategic maneuvering of troops under modern conditions, the continuity of the transportation process has very important significance. At the present time a portion of our Armed Forces along the western axis are located beyond the territorial limits of the USSR. For this reason we must closely tie in the execution of all missions connected with the preparation of networks of communication lines and means of transport on our territory with analogous measures carried out on the networks of communication lines of adjacent countries. This pertains especially to the readiness of rail and motor vehicle roads, as well as to sea transport in maritime theaters of military operations.

Modern warfare creates such difficulties in the organization of troop transport that the fulfilment of these missions can be achieved only under conditions of combined utilization of all types of transport. Even in the last war, depending on conditions, various types of transportation were utilized. Under modern conditions the necessity of our intensive and cooperative operation of the various types of transport has increased even more. For this reason the preparation of communication routes and means of transport for operation in wartime should be carried out at once, proceeding precisely from the problem of their combined utilization.

Let us examine in somewhat more detail the possibilities of utilizing measures for the preparation of each of the types of transport.

Rail Transport. The utilization of railroads in a future war will depend on the conditions of the theater of military operations, the density of networks and other factors mentioned above. If we take the Western Theater of Military Operations, then within its limits, on the territory of countries of the Socialist Camp, the density of railroad networks is 9.2 km per 100 square km, and in capitalist countries it reaches 10.7 km. Such a density of railroads in this theater of military operations, even under conditions of the use of nuclear missile weapons, permits hope of the possibility of carrying out a significant volume of military railroad shipments within the confines of the rear areas of fronts deploying there and in the prefrontal zone. Railroad transport in the internal areas of our country will play a basic role in the total volume of shipments when it is prepared beforehand.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

An extremely complicated mission for the rear services of the Armed Forces will be ensuring continuity of the transportation process from the centers of production (bases) to consumers. In the fulfilment of this mission, we must emphasize, above all, such measures as ensuring dependable operation at the meeting points of railroads of Soviet and West European gauges, and the organization of transloading operations at points where barriers have resulted from enemy strikes (in the destruction of bridge crossings over large water lines and railroad tunnel sectors).

For ensuring uninterrupted supply of our Armed Forces operating in the period of the Second World War on the territory of European countries, along our Western borders were organized ten transloading areas, and a large number of transloading stations were set up.

Such a fundamental system of transloading areas may also be adopted in a future war, but it must be organized with consideration of the new conditions of nuclear/missile war. Each transloading area at the meeting points of railroads of Soviet and West European gauges is a huge military installation and a huge installation of the national economy. It must include several stations with sectors of deep extensions of railroad lines of various gauges, a branching network of motor vehicle roads and pipelines, a communications system, a large quantity of loading-unloading equipment, and specially prepared places for changing the trucks of the rolling stock, as well as transloading bases with depots and means for transporting freight. The degree of prior preparation of transloading areas for operations under conditions of a nuclear/missile war will render a decisive influence on the feasibility of maintaining uninterrupted delivery of materiel supplies from the zone of interior to the distributing stations of the fronts.

Sometimes proposals are introduced to reject transloading areas and to resort, at the initiation of a war, to the altering of gauges of West European lines to Soviet gauges. In the period of the Second World War it was not uncommon to resort to such a measure. Thus, in the zones of operation of the Belorussian and the First Ukrainian fronts, to the line of the Vistula River, most of the railroad lines were altered; later the following main lines were fully altered: Kaunas-Insterburg-Koenigsberg-Marienburg; Bialystok-Tluszcz-Ostrolenka-Deutsch-Eylau; Brest-Warsaw-Poznan-Berlin-Lvov-Przemyzl-Krakow-Katowice-Breslau. Experience showed that to rely upon the alteration of basic

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

main lines is not advisable. This must be resorted to only in exceptional cases, in individual secondary sectors. The alteration of basic main lines may lead to broad gauge lines' cutting the entire network of railroads of European countries into isolated areas, and this will drastically limit the utilization of local transport in rear areas of the fronts and in the prefrontal zone. Along with this there will be insufficient native rolling stock and locomotives in the event of a sharp increase in the length of the network, and it will be impossible to utilize West European gauge rolling stock. Besides, the smaller dimensions of the auxiliary structures on West European gauge railroad lines would make it more difficult to utilize our rolling stock, especially in the organization of two-way traffic on two-way bridges and tunnels. In connection with this we consider it more advantageous to concentrate on ensuring the stable operation of a diversified network of transloading areas at meeting points of railroads of different gauges.

A new and extremely complex problem in ensuring the continuity of transport networks between the front and the rear will be the organization of the surmounting of obstructed places along railroad lines, especially in the internal areas of the country. The most rational form for organizing this operation appears to be the creation of temporary transloading areas (vremennyy peregruzochnyy rayon -- VPR). In the composition of the VPR it is essential to have various special railroad formations, as well as motor vehicle, road, pipeline, loading-unloading, and other equipment. The basic mission of the temporary transloading areas must be the ensuring of continuity in the flow of freight without a substantial decrease in the tempo of shipments during the surmounting of obstructed places until through railroad traffic is restored.

We consider that such organizations should be provided for in the mobilization plans of railroads for operations on railroads of internal areas of the country. To support transloading at water barriers, as well as at tunnel sectors of railroads on the territory of Western countries (outside the borders of operating fronts), it is essential to have rather strong reserves of this equipment which could be moved up to an area where needed in a short period of time.

It is expedient to have mobile formations of temporary transloading areas in the reserve of the rear services of the Armed Forces for aiding fronts to surmount obstructed places.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The volume of reconstruction work on railroads in a future war will significantly exceed the work carried out during the period of the Second World War.

Taking this into account, it is essential to begin serious work on preparation for the restoration of internal railroads and those in the prefrontal zone. In the complex of preparatory work, primary significance is attached to the creation and training of special formations, the prior creation of stocks of repair-reconstruction materials, and others. All these problems in internal areas of the country will be resolved by elements of the transport ministries. However, it is essential for us to submit our requirements now and participate in the measures which are being carried out.

More intensive conversion to diesel-electric traction takes on special significance for railroad rolling stock, will increase significantly the transport capacity of railroads, and will facilitate reconstruction operations. A significant increase must be obtained in the proportion in the car park of large-capacity flatcars and tank cars for the transport of petroleum products. It is extremely essential to create, in the near future, a sufficient park of special cars and flatcars for the transport of missiles and missile equipment, and also tank cars for the transport of the components of liquid missile fuel. The problem of creating a sufficient park of trucks and steam locomotives of West European gauge which may be utilized for movement from transloading areas along railroads of West European gauge in the first days of a war, acquires great significance.

Water transport in maritime theaters of military operations and when there are internal water routes along the axes of combat operations, and in the zone of interior, will carry out a significant volume of troop transport, especially the transport of supplies.

For the preparation of water transport, the problems of organization of transloading areas and outfitting them with equipment capable of carrying out rapid transloading of armaments and all types of supplies from an unequipped shore to vessels anchored in the roadstead and vice versa, should be decided beforehand. It is necessary to carry out scientific-research and experimental design work for the creation of special equipment of sea-going river vessels for the transport of modern types of weapons and ammunition and the development of transloading equipment on board the vessels.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

For the maintenance of water communication routes in a state of constant usability, it will be necessary to create special formations.

In our opinion, it is expedient to have a part of the vessels in the composition of the naval fleets and flotillas adapted so that they are capable of operating at sea and on large river waterways. This will make it possible, in many instances, to avoid the rather difficult operations of carrying out transloading work in roadsteads.

Motor vehicle roads and motor vehicle transport deliveries played a large role in carrying out transport of troops and supplies within a front already during the past war. There were also frequent instances when motor vehicle transport was utilized for delivery of materiel supplies to the fronts in accordance with the plans of the central elements of the rear area, and for urgent transport of personnel replacements. Thus, in 1942 the vehicle park of the Reserve of the Supreme High Command (RVGK) transported up to 1.3 million tons of various freight to the fronts, and altogether for 10 months of 1943 - about 1.4 million tons of freight and 130 thousand personnel replacements.

In connection with the large volume of motor vehicle shipments of the center in the 1941 to 1943 period, the following special military motor vehicle roads of the center were prepared and serviced: Gorkiy-to-Moscow, Moscow-to-Leningrad, Moscow-to-Volokolamsk, Moscow-to-Mozhaysk, Moscow-to-Yukhnov, and others. During the final stage of the war the Moscow-to-Warsaw-to-Berlin highway was in operation.

In modern conditions it is most probable that there will be, not periodic, but constant use of motor vehicle transport along the entire extent of the basic axis from the zone of interior to the operating fronts. Motor vehicle transport will not only have to supplement or duplicate railroad transport, but during a certain period will fully replace it along individual axes.

In modern conditions large motor vehicle highways will be utilized not only for delivery of materiel supplies, but chiefly for the movement of troops in motor vehicles and by mechanized traction, reserves, and all types of replacements. For this reason the role of motor vehicle roads is now growing and qualitatively changing.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

In connection with this the problem of development of a network of hard-surfaced motor vehicle roads arises sharply. In addition, it is necessary to strive to improve correspondingly the transportability and passability of motor vehicle roads on our territory and on the territory of countries of the Socialist Camp allied with us. In an adverse situation the holding up of motor vehicle transport in narrow places and delay in the flow of freight will be unavoidable.

The intensive transport traffic, and enemy actions against important installations of basic motor vehicle communication routes demands the carrying out of serious measures for their maintenance in usable condition and their reconstruction. We suppose, that during the first days of the war the basic motor vehicle highways of the center must be serviced by special road-reconstruction and maintenance formations, which must be capable of carrying out work of technical concealment, reconstruction, and maintenance of the rear area motor vehicle roads.

In the interests of ensuring a high degree of readiness of the road service for operations in the initial period of a war, it appears expedient to carry out large-scale preparatory work in peacetime, taking into consideration the utilization of all forces and means of the military establishment as well as civilian organizations.

A special role in the preparation of military motor vehicle roads will be played by such measures as prior buildup of stocks of construction-repair materials, the procurement and concentration, in necessary locations, of spare structural components for reconstruction of auxiliary structures, the preparation and proper setting-up in peacetime of civilian road organizations equipped with machinery, the development of bypasses of the most vulnerable places, etc.

The motor vehicle park of our country has grown significantly during the postwar period, and is more than 80 percent modernized by the receipt of more highly perfected motor vehicles. For equipping the Soviet Army, especially the motor vehicle transport large units and units of central subordination, there will appear, in ever increasing quantities, larger freight-capacity motor vehicles with large trailers, semitrailers with independent transmissions, and motor vehicle trains. The introduction of this equipment will permit a sharp increase in the freight capacity of transport units and large units and will significantly decrease loading-unloading operations. From this it follows that it is essential for us to

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

submit, in a timely manner, the military requirements for newly designed models of motor vehicle equipment, in order that during mobilization the motor vehicle park of the national economy might, with great effectiveness, be utilized in all elements of the rear services of the Armed Forces in wartime.

A task which cannot be postponed is the development within the system of the Ministry of Defense of essential types of motor vehicles, semitrailers, and motor vehicle trains for transport of all types of missiles, missile fuels, and other special freight for supporting missile troops. Here we are speaking of special motor vehicle transport suitable for operations in the central element of transport.

Pipeline transport is an economical, high-capacity method of fuel transport that has low vulnerability. These positive qualities of pipeline transport are extremely important for the creation of a stable system of supporting modern mechanized Armed Forces in wartime. In the Soviet Union and the countries of the Socialist Camp friendly to us, the network of pipelines is increasing from year to year. At the present time a large program for the development of permanent pipelines is being planned. The Seven-Year Plan for developing the national economy of the USSR provides for the construction of new petroleum and petroleum product pipelines, which will ensure an almost three-fold increase in the length of the main pipelines. Together with this, the construction of the petroleum pipeline from the Trans-Volga region through Bryansk, with branches to the borders of Czechoslovakia and Poland, which has been started, will have special significance not only for the national economy but also for supplying the Armed Forces in the European theaters of military operations with fuel.

In modern conditions it appears extremely essential to force the construction of pipelines within the framework of the Council for Mutual Economic Aid (CEMA), to achieve the uniting of the basic main lines and local petroleum pipelines into a single network of the countries of the Peoples' Democracies. The stability of the support of the Armed Forces in theaters of military operations may substantially facilitate the creation of a system of field main pipelines as an extension of permanent lines. For this reason we consider that the development in every possible way of the production of field pipeline equipment with a pipe diameter of 150 mm has good prospects. Systems of such

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

pipelines with a 24-hour delivery capacity of each line of 2,000-2,400 tons, must guarantee the delivery of basic types of fuel, without overloading, to a depth of 600 km and more from the terminals of permanent pipelines or from operating sectors of railroads.

Air transport, even in the last war, in various instances, played an important role in the transport of troops and their materiel support. It is sufficient to indicate that the forces of the Civil Air Fleet and Long Range Aviation, based upon incomplete data for the period of the war, transported over 300 thousand tons of freight and more than 1.5 million personnel.

Air transport during the period of the Second World War was utilized primarily centrally in the capacity of a resource of the Supreme High Command. However, even during that period there were instances of temporary assignment of certain units of transport aviation to the fronts. Thus, out of the 228 transport aircraft in the Far Eastern Theater of Military Operations during the summer of 1945, 189 were detached for the servicing of the Transbaykal Front. During the time of preparation and conduct of the operation by this front, about 16.5 thousand soldiers and officers, up to 2.8 thousand tons of fuel, and 2 thousand tons of miscellaneous freight were moved by air transport.

In view of the exceptional prospects for the use of air transport under future war conditions, an important modern problem is the long-range increase in freight capacity of the transport aviation pool and ensuring the capability of aircraft to operate from small dirt airfields. It is expedient, even now, to determine the basic axes for utilization of military transport aviation according to the plans of the central elements of the rear services. In order to ensure these shipments it is essential to have powerful central military transport aviation for transfer of troops and to determine beforehand the quantity of this aviation needed by the rear services at the beginning of a war. This will permit timely planning of the utilization of transport aviation of the center, the preparation at the necessary points of materiel stocks, materiel support, airfields, and other means ensuring the uninterrupted operation of transport aviation.

In line with this it is essential for elements of the rear services of the Armed Forces to unfold more broadly the work of resolving problems of airfield-engineering, materiel-technical, and special support of military transport aviation itself.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The enumeration of problems in the preparation of the lines of communication and transport is not by any means limited to those indicated above. However, even those listed, show with sufficient conviction, the necessity of adopting decisive measures for further development of transport.

* * *

The investigation of the problems of the organization of rear services support of the Armed Forces in a future war acquires entirely new significance at the present time.

First of all these questions arise.

Who in the Armed Forces must exercise control of all the means allotted by the State for the rear services support of missile troops, the ground troops, the air forces, and the navy?

What organs are needed in the system of the Armed Forces for the correct distribution and organization of rational utilization of the means of materiel support in the interests of the overall armed conflict?

In our opinion, the only correct resolution of these questions lies in the centralization of the entire matter of the rear area support of the Armed Forces. There are sufficient grounds for such a conclusion both from the scientific-theoretical viewpoint and from the experience gained from past wars.

In May 1919, at the height of the Civil War, V.I. Lenin wrote in The Draft Directive to the Central Committee on Military Unity: " -- the necessary condition for the success of this war is the unity of command of all detachments of the Red Army and the strictest centralization in the direction of all forces and resources of the socialist republics, specifically, of the entire apparatus of military supply, as well as railway transport, as the most important material factor of the war --" (Underlined by us - F.M.) (Collected Works, Volume 29, page 373).

The fulfilment of this demand of the leader of the revolution and founder of the Soviet Army permitted the utilization of the available extremely limited materiel resources of the country in the interests of protection of the young socialist republic during the period of the Civil War with maximum expediency and effectiveness.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

During the period of the Second World War, the General Headquarters of the Supreme High Command was in charge of all resources which the State Committee for Defense allotted for the conduct of armed conflict, carrying out its functions for the rear area support of the Armed Forces through a single central element of the rear services of the Ministry of Defense.

It follows that there is every basis to consider the strict centralization of the entire matter of rear area support of the Armed Forces as an objective necessity. Being guided by such a conclusion, it is appropriate to object to the authors who fight for the creation of a territorial system of materiel [2 or 3 words missing] support in place of the existing elements of the rear services, organized along the principle of channels of military command.

The completeness and efficacy of satisfying the materiel requirements of the Armed Forces in a future war will depend to a significant degree, as indicated above, on the prior accumulation of mobilization stocks, State materiel reserves, and the creation of mobilization capacities of industry corresponding with the proposed groupings of troops and the directions of the armed conflict which evolve. The correct fulfilment of these most important missions, connected with the plans for the development of the national economy of the country, is only in the power of central elements. It will be a drastic mistake if we permit decentralization in this matter among various elements having a limited sphere of activity, according to zones. The division of these missions according to types of Armed Forces is likewise intolerable.

Ensuring the stability of the network of communication lines, for use in wartime by various types of transport, in our country as well as in the countries of the Socialist Camp allied with us, may be achieved only under conditions of unified centralized planning and management. The fulfilment of this mission is tied in with large capital expenditures carried out in accordance with the general plan for the development of the national economy of our country and the Warsaw Pact. For this reason the impossibility of handing over these functions to any elements responsible only for one axis or one area of possible local operations of an operational or even of a strategic grouping of the Armed Forces, is completely apparent.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

We recommend, for the fulfilment of all tasks of organization and control of the rear, the materiel and medical support of fronts and other groupings of the Armed Forces, and the management of all types of transport, that there be a special element in the form of an organ of the Chief of the Rear Services of the Armed Forces in the General Headquarters of the Supreme High Command. The Chief of the Rear Services of the Armed Forces will be able to direct purposefully all the forces and means of rear services support in accordance with future strategic plans only under the condition that he be included in the General Headquarters complement.

The Staff of the Rear Services of the Armed Forces, the central supply, the supporting and transport elements, being under unified management of the Chief of the Rear Services of the Armed Forces, must, in their work, closely cooperate with the General Staff and be guided by its directives. The central elements of the rear services of the Armed Forces must be assigned the missions of organizing rear area support of operating fronts, the troops of PVO of the Country, missile large units of strategic designation and the utilization of production capabilities in the territory occupied by the troops, under the jurisdiction of the Supreme High Command. These elements will likewise carry out the functions of direct management of large units, units, and installations of the central element of the rear services of the Armed Forces deployed in the interior areas of the country, as well as in the prefrontal zone.

In the course of war there may be created high commands in various theaters or axes of military operations in the interests of achieving better coordination of operational efforts of operating front formations.

We consider that in the high command of a group of fronts, in this instance, it will be expedient to have an operational group of the Chief of the Rear Services of the Armed Forces. However, such a group cannot be looked upon as an intermediate supply echelon. The creation of additional supply levels always involves the enlargement of the rear services operations; the introduction of intermediate trans-loading points, in the end result, adversely affects the flexibility of the system of rear area support.

In our opinion, it is expedient to charge the operational group of the Chief of the Rear Services of the Armed Forces attached to the high commands of groups of fronts with rendering assistance to

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the fronts in the rear area support of troops, when the timely information of the Headquarters of the Rear Services of the Armed Forces, emanating from a concretely established situation, indicates a suddenly arising necessity to change the supply plans and carry out an interfrontal maneuver. Herein we allow for temporary subordination to the operational groups of the appropriate central bases created beforehand in the prefrontal zone. The operational groups of the Chief of the Rear Services of the Armed Forces in specific theaters of military operations may be formed also for the fulfilment of certain narrower missions (organization of use of production capacities, putting right the operation of the transportation network on occupied territory, etc.).

The activity of central organs of the rear services of the Armed Forces in a future war has not as yet been sufficiently explored, and it is essential to carry out appropriate work in this sphere. However, we are absolutely convinced that it is most expedient during the organization of rear area support to take as a basis a system which has proven itself: General Headquarters - front - army - troops. This system meets the requirements of centralization to the greatest degree, corresponds to the structural organization of the Armed Forces, and is relatively economical and efficient.

1.3(a)(4)

Perfecting the Methods of Operational Training of Generals, Senior Officers, and Staffs

With the appearance of weapons of mass destruction, especially nuclear/missile weapons, in the technical equipment of modern armies, vast changes have taken place which have, of course, introduced much that is new into the methods of conduct of operations and of warfare as a whole. In searching for the new in military affairs, numerous comrades have recently expressed in publications a number of valuable theses directed toward more rapid exposition of the basic changes that are taking place and the theoretical interpretation and substantiation of the probable nature of armed conflict. The statements by authors of articles in the first issue of the Special Collection of Articles of the Journal "Military Thought" and certain other articles are of considerable interest in this regard.

We fully share the opinions of those comrades who speak out for a fundamental review of the existing basic tenets of the theory of military art, and we think that one of the most important factors assuring successful resolution of this complicated problem is the further improvement of the methods of operational training of generals, senior officers, and staffs. This question acquires special acuity in connection with the numerical reduction of the armed forces and the increase in demands on the officer corps to master the practical skills in troop command. In his address at the All Army Conference of Secretaries of Primary Party Organizations in May 1960, USSR Minister of Defense Marshal of the Soviet Union R. Ya. Malinovskiy, among other tasks of increasing the combat readiness of the armed forces, pointed out the necessity "...to continue to improve the organization and the methods of operational, combat, and political training and to carry out, in a positive fashion, the struggle against the phenomena of oversimplification and weakness in troop training."

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

It is greatly regretted that not enough attention is devoted in practice to the problems of the methods of training troops and command cadres. There is evidence of this in the fact that the forms and methods of operational training during the postwar period have, in essence, undergone no serious changes. The presently existing methods of operational training of commanders and staffs consist mainly of carrying out command-staff and refresher training courses and group exercises with the command complement of district and army troops.

All of these methods of operational training, proven in the past, cannot, in present conditions and in full measure guarantee the qualitative training of command cadres since they are far from comprehensive and perfect. Among the deficiencies we include the following.

In the general system of operational training, the mastery by generals and senior officers of new combat equipment, and particularly of missiles of various designations, has been weak to date. Formally acknowledging the decisive role of nuclear weapons in the destruction of the enemy, and realizing that modern war will be waged with powerful long-range means of combat which in no way compare with the weapons of past wars, generals and senior officers are actually planning and organizing operations as of old, principally on the basis of World War II experience. It is a revelation to no one that methods for reaching decisions, all plans for operations, and other documents that are developed in staffs in the operational training system, differ very little in form and content from what existed during the period of World War II. The methods of training and execution of operations as they are stated in the articles of Comrades Gastilovich and Baskakov, have basically remained as before.[1]

We ask why it is that we conduct the training of troops and command cadres without regard to the basic changes which have occurred in armaments due to nuclear/missile weapons?

---

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In our opinion, this occurs because the military-technical training of generals and senior officers is still inferior. It is precisely because of ignorance of the technical characteristics of nuclear/missile weapons and the means of their delivery to a target that many comrades are unable to evaluate properly the role of these weapons in modern warfare, to utilize them in a battle and operation in a qualified manner, and to assign tasks wisely to the troops utilizing these weapons. By the apt statement of Marshal of the Soviet Union R. Ya. Malinovskiy, not all of us clearly realize what changes have been wrought in military affairs by the adoption of new means of combat and particularly of nuclear and missile weapons. One of the vital deficiencies, as is pointed out by the Minister of Defense, is the inadequate knowledge of the combat potentialities of nuclear weapons and missiles on the part of generals and officers.

Inferior military-technical training of command cadres is explained by a number of circumstances.

Firstly, within the system of operational training to the present time, the practical study of weapons of mass destruction, and especially of the means of delivery of nuclear warheads to a target, is not being planned for or carried out. Military-technical information on these weapons has been gleaned by generals and officers from various manuals, textbooks, military journals, etc. It is quite understandable that this information has been superficial and contradictory. The first four-day refresher training course, for the study of weapons of mass destruction, and principally of missiles of various designations, was held in 1960 in the Baltic Military District on its own initiative. Almost 150 generals and senior officers of the district troops participated in this refresher course. Many of them saw there for the first time those weapons which they "ably utilized" earlier in a battle and an operation.

Secondly, even today there are no textbooks on missile weapons in the military districts. The so-called handbook materials on the organization and tactical-technical data of missile troops that were distributed to military units at various times are very confusing, contradictory, incomplete, and can in no way serve as training aids in the military-technical training of generals and senior officers concerned with the planning for and the use of these weapons.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Thirdly, inadequate reflection on the limitations in the study of even the training data on missile weapons also affects the training of generals and officers adversely. At the present time missile weapons are available to only a few. The majority of comrades who are directly connected with the planning and utilization of these weapons are familiar with these weapons only from the periodical press. It is apparent that in order to have our command cadres really master the art of conducting modern operations, it is necessary to review and broaden the limits of study of missile weapons.

All of these circumstances have undoubtedly played a negative role in the military-technical training of generals and senior officers which cannot but reflect upon their practical activities.

The second deficiency existing in the methods of operational training during refresher training courses and commanders exercises with the command complement of the district (army), is the tendency to study the training problems and the conduct of operations by the methods of group exercises.

In our opinion, the method of group exercises for studying the problems of operational art in the system of commanders' training of the command echelon of a district (army) is unacceptable because it does not conform to the categories of the persons studying and it does not assure inculcation of the qualities necessary for battle, such as rapid formulation of decisions, boldness, and resoluteness in operations.

On the basis of many years of experience, it is known that training of command echelons of districts and armies is usually carried out in two study groups (the commander and the chief of staff) in which all commanders of arms of troops, chiefs of directorates, and departments are included. And within these groups, numbering 20 to 25 persons, consisting mainly of general and officer-specialists (artillerymen, engineers, chemical specialists, rear services troops) and one or two generals (officers) of combined-arms speciality, the training problems of the operation are worked out (determination of the task, evaluation of the circumstances, working out of the decision), which are chiefly the concern of the command echelon. During the exercises, only the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

combined-arms generals and officers are fully and beneficially occupied. As concerns the specialists, they participate only briefly within the framework of their specialities, and for the remainder of the time they are obliged to be inactive. In turn, the generals (officers) of combined-arms speciality also gain very little benefit from these exercises, since the command complement of directorates of the district and armies has sufficient experience for the resolution of such problems as clarification of the task, evaluation of the circumstances, and making the decisions.

As a consequence, the method of group exercises so necessary for a number of reasons in higher educational institutions is not warranted in the training of staffs. Instead of training the command complement of a district (army) in their functional responsibilities and specialities and their skill in the organization of a battle and an operation, because of the existing method of operational training, we unwittingly expend valuable time in the resolution of secondary problems and engender in the subsequent practical activity of generals and senior officers unnecessary verbosity, an inclination toward all sorts of meetings and to hear all types of information and reports.

Proceeding from these considerations, we believe that the method of group exercises utilized in the system of command exercises of the command echelon of the district and army ought to be eliminated and replaced by the method of military-command map games. Depending upon the composition of the military districts and armies and the established training goals, the military-command map games can be single-or two-stage, one- or two-sided. These games, especially the two-stage and two-sided, permit the whole command complement of a district and army to realize conditions more nearly approximate to the combat situation in comparison with group exercises and to load all participants to the maximum with creative activity and to elaborate more fully the training problems and the conduct of the operations.

In 1959 the headquarters of the Baltic Military District carried out a two-stage, two-sided military-command game to which were invited

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

the command complement of the directorates of the district, of the combined-arms and air armies of the army corps, of large units of PVO of the Country, the fleet operational group and also certain chiefs of military departments of civilian higher educational institutions and retired generals. During the game the commanders of armies (corps), arms of troops, and chiefs of directorates acted as the appropriate commanders and chiefs in the composition of a front according to Soviet Army organization, and their deputies - as the corresponding commanders and chiefs within the composition of a group of "Western" armies. The remaining participants in the game performed the duties which coincided with their own responsibilities and specialties. In order to preclude contact between the two sides and to create the most favorable conditions for the game, the sides were located separately--in the district headquarters building and in the officers' club. In content and method of execution, the game received the approval of the participants. For some reason, however, they were not used in subsequent military-command games of staffs of districts and armies.

A third and no less serious deficiency in the method of operational training of the command echelon is, in our view, the fact that staffs of districts participate too infrequently in the arrangements for operational training which are carried out in accordance with the plan of the Center. For example, not one operational exercise was carried out by the headquarters of the Baltic Military District during the past six years. The district troop commander, the chief of staff, and the chief of the operations directorate have not participated in the activities of operational training on a strategic scale for many years now, if we exclude their participation as umpires in the exercises of the Southern Group of Forces.

Such a situation cannot be called normal. The headquarters of districts must themselves participate in the role of trainees periodically and prepare themselves as troop control organs under the immediate direction of the Center. This will permit a significant increase in the effectiveness of the work of staffs, the study of new developments in military affairs, the adoption of experience in the organization of large exercises, and the observation of one's own errors and deficiencies which go unnoticed under normal conditions.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

We realize that the measures carried out by the Center in operational training with the districts involve definite material expenditures. However, it is possible to find methods which would not require large monetary expenditures.

It is also necessary to find methods for improving the special training of army commanders, chiefs of staffs, chiefs of operations directorates (deparments), i. e., those commander-comrades who have direct responsibility for operational and special training of large numbers of generals and senior officers. While the chiefs of arms of troops and services (artillery, PVO, etc.) have increased their knowledge to some degree at special refresher courses during the past years, the above-mentioned category of persons have, for incomprehensible reasons, remained out of the field of vision for many years. Do not commanders and chiefs of staffs have need to study the missile weapons and the resultant revolutionary changes they have wrought in the operational art? Absolutely. And, it seems to us, they also need special refresher courses for the study of the latest equipment and the urgent problems in the field of strategy, operational art, and tactics.

Noting the deficiencies in the existing methods of operational training, we propose a change in the system of conducting the training of generals, senior officers, and staffs since it is obviously antiquated. Our proposals for improving the methods of operational training consist of the following:

For practical study of nuclear weapons and methods of their delivery to a target, military-technical refresher courses for the district command complement, including commanding officers of large units, should be held at the beginning of the training year. During these refresher training courses, lasting 4 to 5 days, there should be study of the new equipment received by the district troops, and chiefly of missiles of various designations. The refresher training courses should conclude with formulation of operational-tactical leaflets on problems of the use of this equipment in a battle and an operation.

Upon completion of the military-technical refresher training courses, and within the time limit fixed by the operational training plan, a two-stage military-command map game should be conducted with the participation of the command complement of the district, of the armies and

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

large units subordinate to the district, and also of the command complement of the other types of armed forces and military-educational institutions that are located in the district territory, and with the generals of the reserve.

As far as possible, military-command games should be two-sided. In this case, one of the sides (main command echelon) must operate in accordance with the organization and tactics of the Soviet Army, the opposing side--in accordance with enemy organization and tactics. This will permit a study in depth of the troop organization and the methods for conducting operations of our probable enemies and, by comparative analysis, the detection of the strong and weak points of both sides.

It is expedient for both sides in war games to be located in different places (buildings) in order that participants do not have the opportunity for personal contact and so that each side carries out its internal control by technical communications means with observance of all rules of cryptographic security (skrytoye upravleniye voiskami-SUV).

The decisions of each side will be presented to the director of the games according to an established schedule and, in keeping with these decisions, combat operations will be developed and new situations will be introduced in accordance with the operational schedule.

The duration of military-command games of a district is 4 to 5 days.

In addition to these undertakings, a district and its armies should conduct one operation command-staff exercise of 6 to 7 days on the spot with the participation of the staffs of combined-arms large units and the staffs of missile units (large units).

In their content, the operational command-staff exercises presently being conducted do not satisfy the requirements for the conduct of modern operations. The majority of these exercises are being conducted too methodically, without sharp changes in the situation. The staffs being educated usually create easy conditions for themselves: the initial situation is presented beforehand at their points of permanent assignment, the decisions made on the basis of the initial situation are put into practice without substantive changes during the entire course of the exercise; changes of location of control points do not take place, the entire activity of the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

staffs amounts basically to the collection of data on the situation and the development of various types of combat documents. Naturally, such exercises are not beneficial to the command complement and they only create incorrect impressions for generals and officers about the nature of modern warfare.

In our practical activities we proceed from the guiding postulate that war can start suddenly. The so-called threatening period will amount to several hours or will be entirely absent. Consequently, the system of staff training must proceed from a more complicated situation in which staffs will be brought to readiness in a limited time and will be dispatched to the reserve command post from which they will assume troop control. Therefore, such undertakings as operational command-staff and staff exercises should begin with calling the staff trainees to alert and imparting to them the initial situation when they arrive at the designated areas from their points of permanent assignment. Prior to the sounding of the alert, it is necessary to take all measures to achieve its surprise effect. Then we will have the opportunity to reveal, although not completely, an accurate picture of the readiness of the staffs for troop control in a complicated situation, and the exercises themselves will approximate combat conditions.

Guided by these considerations, in May 1960, the command complement of the Baltic Military District arrived at the 11th Guards Army without warning and issued a directive to the commander which required the army troops to go on combat alert, to be brought up to combat readiness, and to be regrouped by the combined method on another axis within a limited time for fulfillment of the combat task. All of these measures were to be carried out under the conditions of combat operations that had already been initiated by the enemy. Simultaneously, groups of officers were dispatched to the large units of the army with authority to control the conditions of the bringing to alert of each large unit. During this particular exercise, in addition to the directorates of the army, one division at full complement and only the staffs of divisions and one motorized (tank) regiment each in the remaining large units were alerted.

The commander and the staff of the army had to notify the subordinate troops to bring them to the areas of concentration, plan the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

regrouping over a large distance, brief the troops on the task, and prepare them for march a few hours after the alert was sounded. These requirements were also laid on the troop staffs. Due to the surprise alert, the command complement of the army and the unit staffs were placed in a complex situation and they gained practical work experience in the control of troops under such conditions. Both the directors of the exercise and the participants had the opportunity to observe their own weak spots and gaps in training in general, and in combat readiness in particular.

In our view, operational command-staff exercises to improve the staffs as organs of control should be conducted in complex and sharply changing situations at the front and in the rear, demanding of participants the adoption of new decisions in short periods of time. In the background of this situation, there should be practice in shifting control points by air transport, and also in effecting continuity in troop control among the various command echelons. With these aims, it is obviously advisable to reduce to a minimum the dependence upon the rear services units and establishments which are included in the command-staff exercises so that control points will be highly mobile and efficient.

As an example of how these exercises should be conducted, we can refer to the experience of the front operational-rear services exercise with designated troops which was carried out with participation of Marshal of the Soviet Union A. A. Grechko in the Baltic Military District in June 1959.

In accordance with the directive of General Headquarters (STAVKA), the staff of the front (district) planned an offensive operation and received instructions for its execution. By initial decision, the tank army, which was to enter into the composition of the front during the progress of the operation, made up the second operational echelon and was to be brought into combat on the 3rd or 4th day of the operation. When the operation was already planned, it became known that General Headquarters had the opportunity to transfer the tank army into the composition of the front earlier than the previously designated time and offered the use of it in the first operational echelon on the main axis. The command and staff of the front were placed in

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

a difficult situation and had to replan the operation anew in a limited period of time, pass on the decision to the troops, and to carry out their regrouping. In this episode the staffs obtained considerable work experience under complex conditions.

In the course of the operation, by direction of Marshal of the Soviet Union A. A. Grechko, there was repeated introduction of elements of sharp change in the situation, which resulted in the need for sharp changes in the tasks of formations and large units and there was also practice in alerting the troops and committing them to combat from the march from their permanent billets.

In the final phase of the exercise, a proposal was made to the district staff that it develop and execute an army exercise within a limited period. During the course of the army exercise, by direction of Marshal of the Soviet Union A. A. Grechko, a situation was created wherein the advancing army was forced to change its direction of advance by 90^{o} which, of course, required intensive work on the part of the troops and staffs.

These exercises were a good training school for generals, senior officers, staffs, and troops. It appears to us that operational command-staff exercises should be carried out in just this fashion.

In the arrangement of preparations for command-staff exercises it is expedient for the staffs of a district and of armies to carry out two to three calendar days' staff training on the spot, utilizing communications means to train principally generals, officers, departments, directorates, and staffs as a whole in rapid development of operational documents in accordance with a given situation and in the ability to carry on communications on technical equipment and with cryptographic security documents SUV, during the movement and deployment of control points.

Therefore, during the course of the training year, it is necessary, in our view, to conduct in a district, as operational training, 1) military-technical refresher training courses, 2) a military-command game, and 3) operational command-staff exercises on the spot. In all, 15 to 20 calendar days are required for this training.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

We also consider it necessary and feasible to have the staff of a district participate no less than once in two to three years in an operational training exercise carried out by the Center on a strategic scale. They can be strategic command-staff exercises on the spot with means of communications or strategic military-command map games involving several military districts. When a district participates in a strategic command-staff exercise or game, district measures for operational training inevitably relate to measures carried out by the Center, and the second exercise planned by the district is not carried out.

As concerns military-command maps games on a strategic scale, they can be conducted with the staffs of districts stationed at their points of permanent assignment, and it appears to us that the method for conducting them should be as follows. Having determined the group of military districts that are to participate in the game and the complement of participants from each district, the Main Staff develops the initial situation (tasks) and disseminates it to the participants. The staffs participating in the game are suddenly alerted and proceed to their reserve control points. To supervise the work of the exercise, groups of generals or officers--representatives of the Main Staff and the central directorates, may be dispatched to the staffs of the districts.

In the course of a strategic military-command game, in order to present the plan of the operation and to get agreement on coordination with other districts participating in the game, the commander or the chief of staff of the district along with commanders of arms of troops will go by air at a definite time to the Center and to neighboring district headquarters.

The basic content of a strategic military-command game, it appears to us, must be the resolution of such practical questions as bringing troops up to increased combat readiness during the threatening period, the removal of these troops from a possible enemy strike, the immediate execution of retaliatory nuclear strikes, the elimination of the results of a nuclear attack, and joint operation with the armies of the other Socialist States.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The method proposed for a strategic military-command game does not require large expenditures of material means and will undoubtedly have great benefit in the training of the command complement of the districts and their staffs. The duration of conduct of such exercises should be no more than 6 to 7 days.

Therefore, a total of 20 to 25 days will be required for the operational training of generals, senior officers, and staffs of a district, including the exercises which are carried out on a strategic scale.

It is quite obvious that execution of the measures indicated does not end the operational training of generals and senior officers. The principal method of studying the theory of operational art remains their independent efforts to synthesize and master the developments which are continually appearing in the military affairs.

However, the volume of military literature being published at the present time is so large that one person has practically no opportunity to comprehend, nor even to read, all that is published on various aspects of military affairs. Therefore it would be expedient, in our view, to plan and carry out so-called operational rallies (aktiv) at least once every six months in the headquarters of districts, with the participation of generals and officers of the principal directorates and departments of the district and its armies.

The basic aim of such rallies is to convey to generals and officers of the command complement, in a comprehensive form, the new changes which have occurred during a certain period of time in operational art, tactics, and organization of our troops and those of the enemy. At these rallies it would be possible, within a short time, to familiarize the generals and officers with the basic contents of the most important exercises carried out in the Soviet Army and abroad, to bring changes in troop organization to their attention, and also to review the questions and postulates raised in the order of their presentation in the periodical press. Of course, for these undertakings it is advisable to make preparation and to pass to the audience only those problems in which the solutions disclose fundamentally new tendencies.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

With approximately this same aim, but with a view to special problems, and at more frequent intervals (no less than once in 1 to 2 months), it would be beneficial to plan and to have operational information (operationaya informatsiya) in directorates and departments in the staffs of districts and armies in order that the generals and officers be continually aware of new trends in operational art.

In connection with further improvement of the methods of operational training and the raising of the level of military knowledge of generals and senior officers, there is a need to improve the quality of the training aids being published, especially those on nuclear/missile weapons.

At the present time, there is available to the troops a large quantity of various forms of tables, lines, and graphs for the determination of the basic data for the use of destruction weapons and for the protection of troops against them. But all of these aids were prepared in primitive fashion and by amateurish methods, are inconvenient to handle, and are far from perfect. A tremendous amount of money is expended for the preparation of these aids in the districts. Is it not time to formulate a single, more sophisticated training aid for the whole army by a centralized method and financed by those funds which are being wasted in districts? It seems to us that an affirmative answer to this question will economize on financial expenditures and will provide the staffs with more sophisticated aids for which they have such great need.

The proposals suggested by us for the improvement of the methods of operational training of generals, senior officers, and staffs claims in no measure to be an exhaustive exposition of the problem posed. Therefore it would be desirable to exchange opinions in the pages of the military press in order to discover more sophisticated forms of operational training of generals, officers, and staffs, and then use them to fulfill more qualitatively the requirement of the Minister of Defense contained in the directive on operational training No. 0060.

Major-General M. Ivanov

[redacted]

1.3(a)(4)

[redacted]

-45-

[redacted]

1.3(a)(

[redacted]

1.3(a)(4)

* * *

The general task of any command-staff or staff training exercise on the spot is the training of commanders and staffs for operations in complex conditions of modern combat reality. Whatever the specific arms established by the command for each exercise and whatever the methods used to carry out the exercise, the final aim boils down principally--to training the command complement, preparing the staffs, and continually raising the level of their combat readiness.

It is understandable that the quality and results of an exercise depend to a great extent on the nature of its preparation and organization. In the exercises carried out during the past years, there can be noted a number of negative points common to all of them which, in the interest of the subject, we feel it advisable not to ignore in the future.

The desire to commit the headquarters, not with their existing, but with considerably increased, personnel composition, communications means, and organizational transport is striking. This results in the withdrawal of transport equipment and personnel from subordinate troops, which in turn disrupts the everyday life of units and subunits. Using the personnel and motor vehicles attached to the headquarters for the period of the exercise, there is hasty formation of temporary, disorganized subunits for carrying out such functions as commendant's service and assistance to the "Military Store" (Voyentorg); their personnel are not usually utilized in accordance with their specialties. Commanders and staff officers are placed in a false position because the staffs are brought out for the exercise not as they actually are, but "reinforced" at the expense of weakening other troops. The most harmful thing here is the fact that commanders and staffs become accustomed to participating in

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

training exercises only after definite organizational measures, but the enemy really will not often permit this, especially in the initial period of a war.

The best solution would be to have the staffs being the exercise with whatever composition they happen to have at the moment and to give them some "reinforcements" during the course of the exercise; to teach the commanders and staffs to command and direct with their available, though limited means, and not to place them in an easier and more favorable situation in advance. The example should be set by higher headquarters, chiefly of districts.

The presence at a command-staff exercise of large numbers of umpires is not always expedient, and occasionally is downright harmful, at times not promoting the successful progress of the exercise as much as distracting and tieing up the participants. We are not even speaking about the fact that a significant number of umpires, and especially of their vehicles, at control points very often interferes with the camouflaging of the latter.

These deficiencies are plainly noted when, for example, the commander summons to his field control point (PKP) vehicle or tent one or two subordinate officers but instead, three or four persons arrive, since each person summoned is trailed by one or two umpires. They usually attempt to justify the assignment of so many umpires with the excuse that it is done in the interests of training. But these aims should be achieved by classroom study, by group exercises, and war games. And in reality, a commander will never organize this type of meeting, which in actual conditions would take extra materiel equipment (large tents, transport for their movement, personnel to service them). Frequently the commander and the staff, in preparing to go on an exercise, concern themselves principally with where to billet and how to provide lights and food for the umpires, and in what vehicles to transport them. But after all, this is not the important thing.

The main thing is how to make one's headquarters combat ready and mobile, to set up the headquarters and ensure that its activities are inconspicuous to the enemy, thus guaranteeing uninterrupted con-

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

trol of the troops. Therefore, in preparing for the exercise, its director is obligated to adopt the measures which are necessary to eliminate the concern of the commander and staff conducting the exercise about umpires. One should include only the minimum number of umpires. For the headquarters of a large unit, there should be no more than 5 to 7, and not 25 to 30 persons, as usually happens. In order to observe properly the work of contiguous departments and specific individuals it is advisable to combine the work of umpires and to assign one person for 2 or 3 departments, e. g., for the operational and intelligence departments, the rear services, special services, artillery, and aviation. In case of extreme necessity it is possible to assign an assitant to certain umpires. In this situation, it will be less crowded and the participants will work more independently with more interest. During the course of the exercise, the secondary personnel will be under the management of the commander, the chief of staff, and the chief of the department. Therefore, 5 to 7 qualified officers of the senior staff will be enough to instruct and to check a subordinate commander and the staff of, let us say, a division or corps.

It is particularly desirable to note the role of terminal umpires (kontsevyy posrednik), if they are present at the exercise. First of all, it is necessary that they be located in operating areas and that the commander and his staff participating in the games should have communications with both the umpires and their subordinates by the actual means that are possible in the given situation. An exercise does not achieve the desired results when the terminal umpires are located at reduced distances. It is necessary that the terminal umpire fulfill the will and orders of the commander if they are not incomprehensible. The director of the exercise must so instruct the umpire as regards decisions adopted by a commander. It is not possible to acknowledge the following situation as procedurally correct. Having assigned a subordinate (final umpire) the ~~task~~ TASK of an offensive in the mountains, the commander categorically required him to make a broad enveloping maneuver, utilizing the many available routes. The terminal umpire acted incorrectly, and against the commander's orders, hit the enemy "head-on", met with no success, and during the critique the director

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

of the exercise rebuked, not the terminal umpire, but the participating commander.

Neither is it possible to tolerate the fact that with the wide use of liaison aircraft and helicopters in all branches of the national economy, through the fault of the command, they are used very little or not at all in command-staff exercises. In the event of a restriction in the operation of radio communications, the participating commander and his staff are obliged to utilize only vehicular transport, at a time when the helicopter (airplane) would be an incomparable means of liaison if you consider that the troops will usually be located at great distances from one another.

The problem here is certainly not in the real economy of resources but in the fact that in "departing further from sin" and from superfluous "extraordinary occurrences" (ChP), we do not train the commanders and staffs to fulfill important responsibilities by mastering air transport (selection of landing areas, concern about materiel support). Furthermore, we neither teach nor train commanders and staff officers in observation, reconnaissance, and orientation from the air. This is a very serious gap in the conduct of command-staff exercises. For corroboration of the above, we shall cite an example from the experience of the command-staff exercise of the Turkestan Military District which was carried out in 1959. The day before the start of combat operations the commander of a large unit was summoned for clarification of his task to the senior commander's headquarters, which was located at a great distance from the large unit. The commander, taking the deputy chief of the operations directorate with him, proceeded by vehicle to the airfield, expending four hours of the night going cross country. Upon arrival at the airfield, it turned out that the commander did not have to make the flight. He returned to his command post (P) in another 4 hours, just 30 minutes prior to the "attack". The deputy chief of the operations directorate returned by airplane from the higher headquarters to the area of location of his own headquarters on the second day of operations and, in his own words, found the headquarters, but the pilot, not being trained for operations under these conditions, was afraid to land. The officer returned to his

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

headquarters after the end of the exercise. The above again corroborates the fact that at the tactical level (zveno), not to mention the operational, it is necessary to utilize air transport more widely for the control of troops and to train officers and staffs as a whole to use air transport more sensibly.

Two-sided command-staff exercises are carried out in an interesting fashion, but they demand great flexibility of the command echelon in the course of the exercise and also adequate communications with the umpires of both sides, in order to permit correct reaction in good time to the decisions adopted by the sides. For example, if the "northern" troops depart at 1700 hours from their areas of concentrations to new areas, it is not possible to evaluate positively the results of a strike by the "southerners", carried out against these areas after the departure from them of the "northern" troops.

Another example. The results of the action taken by the "northern" side created favorable conditions for the landing of a tactical airborne force in the rear of the "southerners", which was carried out after the necessary substantiations and calculations. The senior umpire of the "northern" side noted all of this. However, when this matter reached the director of the exercise, he changed the conditions radically, "annihilated" the "northern" airborne force, and "threw back" their left flank for a considerable distance, to the benefit of the "southerners". Such lack of understanding between the director and the senior umpires cannot pass unnoticed by the participants, as well as the fact that at exercise critiques, quite correct actions by one or the other side are declared incompetent and incorrect without any basis.

In two-sided exercises, the sides must receive particularly precise results of reconnaissance of targets in the depth which cannot be observed from the ground, especially if there are no actual means of reconnaissance available to the participating staffs. In order that the exercise proceed with great interest and in order that the assignment of tasks to reconnaissance and the receipt of its results be made more concrete and substantial, it is expedient in command-staff exercises to use realistically simulated means of reconnaissance, particularly aerial reconnaissance.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Depending upon how and when the reconnaissance, communications, and control of intelligence organs is organized, the latter are responsible for furnishing pertinent information on the enemy which must arrive at the headquarters via actual means of communications, for example: by radio from an artillery fire-adjusting plane; from a staff officer observer in a helicopter, reconnaissance plane, or bomber; from a reconnaissance group dropped into the enemy rear; radio intelligence from a higher headquarters, etc. But the content of this information and the nature of its arrival must be as close as possible to those of a real situation.

Completeness of information on the enemy is frequently dependent, not upon well-organized and well-directed reconnaissance, but upon how persistently an intelligence officer follows "on the heels" of the umpire and peers at his map.

At command-staff exercises carried out on the spot, many opportunities exist to organize and carry out reconnaissance with realistically simulated means and even with actual reconnaissance subunits. This is especially important in two-sided command-staff exercises. Of course, there must be designated persons (umpires) in helicopters, airplanes, and subunits of troop reconnaissance who, depending on the nature of the operations of the crew (subunit), will be responsible for furnishing the necessary information and relating this information to the locale which a given crew is observing. In the capacity of umpires, in airplanes (helicopters) and in subunits, it is expedient to have the commanders of these subunits, who will be able to instruct their subordinates in the conduct of reconnaissance simultaneously. This means that the subunits included for this purpose must be composed of their own standard complement and not of a contrived one.

In recent years, units and large units of troops have begun to participate more frequently in command-staff exercises where, as the background of a given exercise, they develop a definite theme in the program of combat training and examine some particular problem. Undoubtedly the inclusion of these troops raises the interest of the participants of the exercise and compels them to be

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

more careful in considering the situation and in calculating time realistically; it obliges them to keep in mind the presence of troops; to be attentive also when resolving problems of materiel supply, which frequently are simplified in the absence of actual troops. In the course of the exercise the command echelon must not forget the participating troops, but must train them also. The deputy commander of troops, in particular, must be responsible for this.

At times, due to a number of reasons (hindrances due to sowing of crops, which creates a lack of sufficient motor vehicle transport, etc.), it is expedient to have the troops participate only in certain stages or phases of the exercise. It is always permitted and is never advisable to decline, to simulate troops as subunits of motorized infantry, tanks, artillery, other arms of troops, and also of aviation. This is always justified and will make the exercise more interesting and instructive. The execution of command-staff exercises with simulated troops has special significance now for skeletonized (skadrirovannyy) large units and units and for units and large units maintained at reduced complement. However, even with simulated units, the commanders and staffs must operate in realistic areas and not in reduced areas.

In conclusion, it is advisable to note once again that any command-staff or staff exercise will be more beneficial and instructive only if the staffs participate in the exercise at the strength which they actually have, at the strength in which they will be caught in a real situation, without extra preparations calculated for show and effect of equipment. It is necessary to give the staffs only a strictly limited time period for preparation to go on an exercise or to put them on the alert and place them in conditions close to actual reality.

The Submarine Operation of the Navy - the Naval Operation of the Future

by

Admiral Yu. Panteleyev

In the past war the principal enemy of the fleet at sea was the aircraft armed with torpedoes and bombs. This is attested to by the statistics on losses of combat vessels by the nations involved. Whereas, in a number of instances, a vessel could evade a submarine and then even pursue it, the evasion of an aircraft by a vessel was very difficult, and the overtaking and destruction of a departing aircraft was completely impossible. It was hindered in this by its significantly slower speed and by the limited ceiling of its antiaircraft artillery. In other words, in comparison with an aircraft, a vessel possessed neither the maneuverability nor the requisite firepower.

The submarine has actually remained all-powerful ever since World War I.

In our time the aircraft and the submarine have become the major enemies of that leviathan of combat fleets, "the king of the oceans" - the battleship. And this leviathan, which costs billions, has departed from the seas and oceans in ignominy; all naval powers have stopped building it. The same fate has also befallen other large combat vessels. The missile/nuclear weapon has become the basic means of destruction even at sea. Its development has led to the division of naval power into two parts: one part, consisting of nuclear/missile delivery vehicles immeasurably smaller in size than the old battleships and cruisers, has taken to the air (jet aircraft); the other has gone under water, into the depths of the seas and oceans (the submarine fleet).

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

We visualize a future armed conflict primarily as a battle in the air and underwater. Moreover, where air operations have their own clear-cut organization and definite composition, the concept of "submarine operations" is entirely new and not reflected in our literature, and has not yet received the "rights of citizenship" in our naval art. Is this right? It would seem not. This conviction evolves from the following considerations.

The study of the history of military operations at sea in past wars must be carried out neither exclusively nor largely for the purpose of learning and defining the course and results of the events themselves, but rather for establishing the new trends in naval art which took place in a given war, what the prospects are for their development, and what results they might produce.

It will be recalled that "submarine warfare" has been mentioned more than once in naval art. The Germans especially declaimed about this; nevertheless, neither in the First nor Second World War, after having declared merciless submarine warfare against the Allies, were they able to bring the Allies to their knees. After carrying out a series of bandit attacks against hospital vessels, and after gaining, unquestionably, certain operational-tactical successes, the German submarine fleet was still unable to achieve any kind of strategic goals with submarines alone. Although partly disrupted, the supplying of England proper was not stopped. The failure of German "submarine warfare" is explained by the fact that their submarines,although able to sink enemy vessels at sea, were not able to demolish his military economy entirely, to destroy the basis for the construction of new vessels, and to crush the antisubmarine defense. For each transport sunk toward the end of the war, the Allies constructed two which were more modern.

Thus, in past wars submarines primarily carried out operational-tactical missions; strategic missions were not within their power to accomplish, primarily because of the status of equipment and the organization of the submarine fleet of those days.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Is it correct at the present time to raise the question of the organization of purely submarine operations as naval operations of the immediate future? It seems to us that it is. Moreover, a delay in deciding this question can cause harm to the future increase of the defensive power of our country.

First of all, let us attempt to define submarine operations. The meaning of "operation" as a form and method of achieving operational or strategic goals has a very definite connotation in our military art; it is known to the reader and there is no sense in citing it here. Let us agree beforehand that we do not admit the possibility of resolving all missions of a war, or the achievement of its strategic goals, by any one type of armed force. Victory in war can be achieved only through the combined efforts of all types of armed forces in cooperation with one another. Therefore, we view a submarine operation as an integral part of battle by the armed forces in a naval theater, carrying out the performance only of particular operational or strategic tasks.

By a submarine operation we mean an operation of submarine forces which is conducted in the depths of the ocean or the sea without rising to the surface. The term "underwater vessel" was not applied accidentally. The designation "underwater boat" appears to us to be too general, inexact, and not at all suitable for operational-tactical language. At the present time there are missile-carrying submarines with a displacement of several thousand tons, submarines for antisubmarine defense, and submarines of other designations. It is natural, therefore, that a generic understanding be developed for all submarines, whether the submarine fleet or submarine forces which operate in their own peculiar element - in the depths of the oceans and seas.

A purely submarine operation can take place only when purely submarine missions are carried out in ocean depths by a submarine fleet and where the possibilities exist for their fulfilment by submarine forces. In the immediate

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4

[redacted]

[redacted] 1.3(a)(4)

future, just as at present, the submarine forces may conduct operations primarily in conjunction with the aviation and, in some instances, also with the surface fleet. But such operations will not be designated submarine operations; it would be more exact to call them operations of submarines.

As is known,at present submarines operate in close coordination with aircraft and surface vessels which are supporting their operations. We devote a great deal of attention to this problem. Much is said about aerial reconnaissance on behalf of submarines and about the support afforded by surface vessels to the deployment of submarines from their bases or to their return. Some of these situations have become prescribed requirements. During any naval exercise a thorough minesweep of the channels of a naval base is instituted directly prior to the departure of the submarines from the base. Also, in order to support this departure of submarines, all antisubmarine defense forces (protivolodochnaya oborona - PLO) in the area of the naval base are deployed. (We have in mind destroyer escorts and aircraft of PLO.) Finally, a special direct escort is organized to support the departure of submarines from the bases. This great number of ships at sea and aircraft circling about, all engaged in driving off enemy minelaying submarines and in "sweeping away" mines, without even knowing if there are any at all, most blatantly reveal that an operation is being prepared.

Even during the past war a number of measures for the so-called support of submarine deployment started to become outmoded, while submarines more and more gained the right for complete independence of action. Today this trend is becoming evident with an even greater force. Of course, the execution of all or part of the measures indicated above is not excluded even now in certain cases. However, it is entirely clear that such methods for supporting the deployment of submarines or supporting their combat activity are rapidly becoming outmoded and it is necessary to seek new measures.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

One more example. In order to force the enemy antisubmarine defense line with our submarines, it is considered essential to carry out decisive strikes from the air and sea against his PLO forces. But the execution of this strike makes it patently clear that our submarines are getting ready to force that particular line. In this manner, our actions will serve as a distinct combat alert for the enemy PLO. Is it not time for the submarine forces themselves to secure the forcing of the PLO line covertly underwater, without all the uproar on the surface of the sea and in the air? It seems to us that such a time is here, or practically here. Evidently, operations for forcing the PLO line will constitute one of the first submarine operations of the submarine forces.

What kind of operational and strategic missions can the submarine fleet resolve independently because of this developing situation?

As is well known, the military leadership of NATO countries still attaches special significance to its aircraft carrier large units, viewing them as mobile airfields from which aircraft can take off with nuclear weapons. According to the plan of the NATO leaders, these "airfields", being mobile, must be in their positions at the right time in the Atlantic, in the Norwegian Sea, and in the Indian and Pacific Oceans, from which they can destroy designated targets on the territory of the USSR.

Aircraft carrier large units, the fleet's"Enemy No. 1", are powerful but far from invulnerable. They can be destroyed, first of all, by missile strikes of our aviation. But the enemy may try to create strong counteractions with his PVO forces and weapons against these strikes. At the present time it is extremely difficult to conceal the deployment of large masses or of separate groups of aviation and their approach to aircraft carriers, because the eyes of the enemy have become very keen and his ears sharp. The "sudden" appearance of strike aviation from behind the clouds is also excluded, inasmuch as to bank on the inadequacy of enemy equipment or on errors by his leadership is worse than foolhardy. Aircraft also cannot

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

"hover" in one zone for a long time, awaiting the arrival of the enemy. For the enemy can deploy his aircraft carrier strike large unit (avianosnoye udarnoye soyedineniye - AUS) prior to the beginning of a war under the most plausible pretexts (cruises, training exercises, etc.).

The submarine fleet possesses incomparably great capabilities for combat with the AUS. It may be deployed in complete secrecy, during the period of exacerbation of the military-political situation, to those very areas of the ocean or sea, designated by the enemy as zones for the deployment of his forces for a strike against our installations. And it may very well be that the enemy aircraft will not have time to take off for the delivery of a strike, as they will go to the bottom together with their "airfield" after being attacked by nuclear weapons of the submarine forces which had been covertly deployed beforehand in the appropriate areas of the ocean or sea.

For the execution of an independent submarine operation to sink the enemy strike aircraft carriers, is it sufficient to have only atomic submarines with nuclear weapons? No, it is not sufficient! The resolution of this mission requires an entirely new organization of large units of the submarine forces. In the interests of ammunition supply and technical servicing, submarines are still grouped in large units on the basis of class and type (submarines with atomic engines, submarines with diesel engines, submarines with torpedoes, submarines with missiles, etc.). Such large units are not suitable for carrying out independent submarine operations.

Upon receiving a combat mission to destroy an AUS, a submarine (or a group of them) must, at the present time, first of all be guided to the target either by aircraft or by a reconnaissance screen of submarines. The commander of an attacking submarine does not see or know who is providing his tactical support or where it is and is forced to operate independently; he watches nothing except the target. Submarines beneath the surface do not yet represent dependably controlled large units.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

It appears to us that it is now essential to create separate submarine large units capable of independently resolving tactical or operational missions. We have in mind submarine squadrons of vessels with atomic propulsion. Such a squadron must consist of strike submarines (with missiles and torpedoes), reconnaissance submarines with powerful hydroacoustical equipment, antisubmarine defense submarines, minelaying submarines, and supply submarines. Upon receiving its combat mission for operations in a prescribed area of the ocean or sea, the submarine squadron, independently, with its own submarine reconnaissance forces, must find the assigned target and direct its strike forces against it. On the basis of his intelligence data, the commander of the operation must plan the main direction of the strike and determine the forces to be used against the main target, the operational makeup of these forces, and the forces to be used in a strike along the auxiliary axis. In a number of instances the covert laying of mines (anchored or floating) may delay enemy deployment and in this manner support the operations of the strike submarine forces. It is doubtful that the existing hydroacoustical equipment of the enemy will be able to determine accurately the entire depth of the operational makeup of the submarine forces and the large number of attacking submarines deployed at various depths. In any event, the ranges of this equipment are still much less than the ranges of our modern long-range torpedoes, let alone missiles.

It is evident that an ocean-going atomic submarine, carrying powerful nuclear armaments, must have its own reliable defense under water from enemy submarines (antisubmarine defense) and from mines (while moving at corresponding depths), in order that the submarine commander can devote all his attention to the major task - the attack of the assigned target. With the development of the means of underwater television, sonar, and communications, the control of a submarine squadron becomes possible and submarine battles and engagements with all their underwater aspects - reconnaissance, deployment, strikes against protective forces and against the main target - assume realistic forms.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Of course, an operation for the destruction of an AUS may be conducted, as we have already indicated, either by aircraft alone or in coordination with submarines. We do not exclude such a variant, for it does not contradict the basic views indicated above. But we reiterate that even for joint operations with aircraft, the submarine forces must be organized along a new principle. This is primarily necessitated by the strengthened defense of the AUS and by the rising cost of atomic missile submarines, which require considerable support in all their operations. (We have in mind reconnaissance, PLO, and PVO, i.e., those types of defense which a battleship required for itself on the surface of the seas in its time.) It can be said that since "naval power" has gone under water, all of its defense must also go under water.

We have already spoken of the impossibility of aviation's remaining a long time in waiting zones, of its significantly lower capability than submarines for covert tactical deployment, and of the great dependence of aviation upon the condition and availability of an airfield network. To this must also be added the dependence of aviation capabilities upon the weather. Thus, by no means can aviation always guarantee the complete success of its operation against the AUS on all expanses of the world's oceans.

The struggle for securing the possibility of the first strike in the initial period of war will be an important problem for both sides; therefore, in a number of instances, the operational deployment of forces even during peacetime will be unavoidable. Even today submarine forces can occupy necessary waiting positions and from them conduct covert and prolonged observation of the enemy. Aircraft cannot do this. Sonar is incapable of determining either the hull number or the designation of a submarine; for this reason, during an intermittent sonar sounding for submarines it is difficult to determine immediately the number of submarines operating in a given area, since the same submarine may be detected several times.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

We are correct in asserting that "underwater danger" is more serious than aerial danger, for it is more difficult to gain rapidly the particulars of an underwater situation than of an aerial one. After intercepting the enemy, the submarine forces are capable of delivering strikes against him repeatedly and of organizing a pursuit while reloading their torpedo nuclear weapons underwater. All these considerations speak for the advantages and the reality of submarine operations.

Although recognizing the vulnerability of aircraft carriers from the sea, as well as from the air, foreign authors for the time being are still timid but, nonetheless, are expressing views on the growing obsolescence of aircraft carriers as floating, maneuverable "airfields". The attention of these authors is turning to missile-carrying submarines which can use their missiles from the depths of seas and oceans and, especially, from the areas of the Arctic (through the many unfrozen patches of water in the midst of ice) where an aircraft carrier cannot operate at all. It is natural, that in contrast to the AUS, with its numerous support vessels and aircraft, the appearance of our missile-carrying submarines in the ocean and their tactical deployment at great depths can, as we have indicated, be carried out covertly without the knowledge of the surface fleet of the enemy, his aviation, and, even more so, the shore facilities for the detection of submarines. Neither aircraft carriers nor the most powerful aircraft can counteract the arrival of submarines in the Arctic area. The sinking of one or two submarines during their passage into the Arctic by surface vessels or aircraft will not have a decisive effect. In the near future only enemy submarines will be able to counteract the deployment of our submarines. And only our submarine forces, organized into submarine squadrons and carrying out submarine operations, can counteract this formidable force of the enemy.

We shall discuss briefly the plan of operations for the destruction of enemy missile-carrying submarines in the Arctic area, i.e., under the ice in the depths of the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Arctic Basin. Here, neither an aircraft nor a surface vessel can aid a submarine in the usual manner in any way. Our submarine squadron (a large unit of submarine forces in a given theater) must first of all have its own underwater reconnaissance, consisting not only of reconnaissance submarines but also of technical equipment for submarine detection, installed by special minelaying submarines under the ice (buoys for detecting enemy submarines, mine obstacles, and nets). The creation of such means is not an insoluble problem. In addition, our strike missile-carrying and torpedo submarines for combat against enemy missile-carrying submarines in the ocean depths under the ice must have a mobile underwater patrol and a direct underwater defense consisting of PLO submarines and submarines for detecting mine obstacles (submarine mine detectors, a type of submarine mine-sweeper). A squadron commander must command such an operation from one of the submarines. Control of the forces must be based on reliable means of underwater communication and television. The validity of such an operation has already become apparent; however, the materiel base for its resolution is still more theoretical than practical. Let us recall that this is not the first year that American atomic submarines have studied the under-ice Arctic area.

During the conduct of submarine operations it is absolutely necessary that each submarine know its place in the formation and its place in relation to the bottom of the ocean or sea and to the nearest banks and islands, first of all for security of navigation, as well as for the tasks of tactical deployment and placement of technical means of combat (buoys, mines, nets). One of the most important navigational aids for helping submarines determine their position must be a well-made naval chart showing depths of the Arctic basin and a series of other important data (underwater currents, the steepness and unevenness of the bottom, as well as its characteristics). Such a "submarine" chart should be in the making now and should be periodically updated with new data (areas of sound channels and other hydrological elements) for the most detailed portrayal of the entire underwater environment. However, the availability of even the most detailed charts

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

cannot guarantee that there will be an exact pinpointing of the submarine's position. A question arises concerning the creation of underwater hydroacoustic beacons for submarines, concealed from the enemy and operating when triggered by our submarines. Theoretically, the creation of such a beacon, operating on the basis of a coded format, also presents no problem.

We do not deny, of course, the possibility of submarine forces' detecting enemy submarines through the use of technical equipment installed on the ice surface or in the water through holes cut into the ice. But in view of the great mobility and hummocking of Arctic ice and of the vulnerability of these technical means from the air, it should be taken into consideration that these technical means will be used only occasionally. Therefore, they should not be the principal basis on which the reliability of an entire submarine operation is planned.

Thus, we arrive at the conclusion that combat against missile-carrying submarines under the ice in the Arctic is exclusively a submarine operation, in which the participation of other types of armed forces is completely insignificant. On the basis of all that has been stated, it is now time to consider the creation of submarine sailing directions for the seas and oceans.

Combat with enemy missile-carrying submarines outside the Arctic basin must be planned on the same principles as those in the Arctic. To escape aerial and surface pursuit, modern enemy atomic submarines more and more are increasing the depth of their dives, which are now measured in hundreds of meters. In our time, it is not the structure of the submarine itself, but the depth of the sea or ocean, that will soon limit the diving depth. Combat by our submarine forces against enemy missile carriers at great depths will also be a purely submarine operation with all its inherent characteristics.

The significance of the potential enemy's communication routes from America to Europe, across the Atlantic Ocean and, to a lesser extent, the Pacific Ocean, is well known.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4

It is necessary to understand correctly the composition and role of ocean shipments in order to assign a mission to the fleet skilfully and to select appropriate forces for the resolution of that mission without expecting more from them than they can accomplish and, at the same time, not assigning them missions which are impossible for them to carry out. Strikes against a convoy on the communications routes, carried out by a group of submarines or by aircraft, can destroy part of the guard vessels and part of the transports. However, this will have no perceptible influence on the situation on the ground front or on the course of the war as a whole, for in a given instant only tactical success is achieved at a time when all ocean communications routes as a whole will have strategic significance. The results of a strike against a convoy must not be judged by individual transport sinkings out of an entire convoy, but by the sinking of the entire convoy, or at least three-fourths of it.

It should be remembered that in a number of instances even the destruction of a convoy in its entirety will not by any means immediately influence the situation at the front, in a campaign, or in the war as a whole. This is all the more reason why it is necessary to destroy a convoy and not to settle for partial tactical successes in the battle against communications routes.

How, then, and by what means, can the destruction of an entire convoy be achieved, a convoy which in a number of instances will proceed in separate groups (large units) which do not fall into the zone of one nuclear bomb? In addition, it should be taken into consideration that some of the vessels will proceed without cargoes for purposes of camouflage.

In the immediate future the resolution of an assigned mission only by missile forces from our own territory is not yet very realistic, since an enormous number of missiles will be required even for one convoy of 100 transports with its escort if a high rate of probability for its destruction is desired. In resolving this same mission aviation will require reliable, uninterrupted reconnaissance of the ocean

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

and, since it is capable of only a single attack, will not be able to reload in the air, but will be forced to return to the airfields. We are by no means deprecating the significance of strikes against convoys by aircraft, but we must also note all the weak spots of this type of force.

The matter is different insofar as the capabilities of submarine forces are concerned. Even now, unlike aircraft which can only search for hours, submarine forces can search for convoys independently underwater for tens of days; they can wait until the convoy approaches, overtake it and, without surfacing, take up advantageous positions; then they carry out strikes against the escort forces, break through them for strikes against the transports, and moreover, deliver these strikes repeatedly with the use of underwater nuclear explosions. Naturally, the strike of one submarine squadron will serve as reconnaissance and guidance for another, which can, in several hours, deploy for the completion of the first squadron's strikes against the convoy.

At the present time, and for the immediate future, it is difficult to assume that the enemy convoy escort will quickly and easily detect all the submarine squadrons (2 to 3) deployed in a given zone of the ocean at various depths and be able to determine where, how many, and what type of submarines are deployed. Atomic submarines will always have superiority over a convoy in speed with all the benefits ensuing from this, including the guarantee of concealment of actions.

The place of departure of convoys and their place of assembly at sea can be established not only by aviation, but by reconnaissance submarines; and in the future the entire mission for the destruction of a convoy can be resolved completely within the framework of a submarine operation. It should be kept in mind that the development of PVO means makes aerial reconnaissance very complex and less reliable than reconnaissance with the aid of submarines.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The parameters of a submarine operation for the destruction of a convoy are already indicated. In its battle against communications routes the German-Fascist fleet adopted "wolfpack" methods with the use of reconnaissance submarines. And only the weakness of technical means during the period of World War II - the lack of underwater television and means of reliable covert communication, prevented the Fascists from resolving the problem of submarine operations completely. Allied communications routes were not disrupted. At the present time the means and methods of radiocountermeasures in our country and abroad have improved significantly. The achievements in this field are not to the advantage of guided missiles and aircraft but do not at all affect the ocean depths, where the means of hydroacoustic concealment and counteraction by submarines are still a long way from results capable of decisively breaking up a maneuver and strike by submarine forces.

Thus, a submarine operation during operations against enemy communications routes becomes plausible in all respects. In a given case we also do not exclude the coordinated operation of submarines with aircraft when this is possible, we say, that a purely "submarine operation" is more effective when it is conducted with decisive goals in mind against communications routes where not a single, but a prolonged and methodical, action is required.

To the extent that the threat to sea communications routes from missile strikes increases, a future war could, unquestionably, see the appearance of submarine tankers, submarine vessels for transporting troops and cargo, and, finally, special submarine amphibious-force-landing vessels. During the past war there were attempts in our country and abroad to create submarine transports. Thus, we delivered ammunition and supplies by submarines to the besieged naval bases of Hanko and Sevastopol. True, these were not special submarines,but combat vessels with limited capabilities for taking on various cargoes, but the idea of creating submarine transports and underwater communications routes received its first practical application.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Thus, in a future war there will undoubtedly be missions for the destruction of enemy underwater communications routes and for the protection of our underwater communications routes. It is apparent that missiles and aircraft will not be able to destroy submarine transports in the ocean and sea depths. Of course, it is possible that they could achieve partial tactical successes as a result of an underwater atomic explosion capable of destroying one or two submarine transports. However, these successes will not lead to the breakdown of communications routes or to the disruption of deliveries over them.

Underwater communications routes will be at various depths and along different courses, and the submarine transports will proceed in a dispersed manner. Under these conditions, who will be able to find quickly and destroy such a submarine convoy? It is apparent that only properly organized submarine squadrons of the submarine forces are in a position to resolve this important operational and, in a number of instances, even strategic, mission. Aircraft and, even more so, surface vessels, certainly cannot do it.

It is necessary to mention certain special missions which, though not tied in with strategic tasks, have come up in the past and apparently will face the fleet in the future. We are referring to diversionary operations of different magnitudes, carried out for the purpose of destroying radar stations and radio stations of communications of special designation, and also to resolve other missions of the most varied nature, especially on islands or on a sparsely populated and poorly protected shore. These missions cannot by any means always be resolved by a missile, no matter how it may be delivered. Modern technical means permit an installation to be reliably protected even from a ground nuclear burst. Very frequently it will be necessary not only to knock this or that installation out of commission, but, what is much more important, to obtain documents and seize the "tongue". Neither an airborne landing nor a missile can accomplish this mission.

For the resolution of a number of missions of a diversionary nature the temporary presence of subunits of our armed forces at an enemy installation will be required.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Only submarine forces can suddenly and covertly land such a force and also quickly and covertly remove it. In past wars there were many examples of such use of submarines, but the scale of these operations was limited.

We have reviewed a number of operations, the aims of which, in our opinion, can most effectively be achieved even today by submarine forces and even more so in the immediate future. We have discussed the destruction of aircraft carriers and missile-carrying submarines, the disruption of surface and underwater communications routes in oceans and seas, and certain diversionary actions of submarine forces.

This is, of course, far from a complete list of all of the missions which could be assigned to the navy and, especially, to its submarine forces. To this should be added the contribution of missiles fired by submarines against naval bases, shipbuilding yards, and other enemy military installations located on shore and in the zone of interior of the enemy country; also, missions involving coordinated action with troops of our maritime front by landing forces in the enemy's rear. However, it appears to us that while these missions can be assigned to our submarine forces today, in the future they can be accomplished with equal success by missile units and long-range aviation. In the resolution of these missions, strategic missiles will completely replace submarine forces, but nothing can replace submarine forces in their battle under the ice and in the depths of the oceans and seas against enemy missile-carrying submarines, his submarine transports, and his aircraft carrier strike large units. Therefore, the question arises as to whether it would not be better to orient our submarine forces in the future chiefly toward those types of operations, the execution of which depends entirely upon them, and in which a missile (ballistic or from an aircraft) cannot at present replace a submarine? Without exception, every type and arm of the armed forces must first of all execute those missions which it has been designated to accomplish and which no one else can accomplish.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

It was not just for sport that our naval reconnaissance seaplanes (MBR-2) bombed troop concentrations on the ground front at Leningrad during the first months of World War II. Of course, during this period no one conducted aerial reconnaissance at sea, since it was impossible in those days to replace a naval reconnaissance plane with any other aircraft - all aviation operated on the ground front. Many seaplanes were lost, but the grave situation at the front at that time necessitated such sacrifices. Such use of naval aviation cannot serve as an example for the future, for this was a unique and atypical case for methods of conducting military operations at sea.

The approach of our missile submarines to the enemy shore to carry out a missile salvo will always entail their entry into the enemy antisubmarine defense (PLO) zone; therefore, if the salvo is carried out from a distance, outside the PLO zone, from an area of complete security (more than 500 to 600 miles from shore), then is it not better in such a case to use the ballistic missiles of the missile troops or to use long-range aviation? For the ocean-going atomic missile submarine is a very expensive weapon; it not only carries expensive equipment, but large groups of highly qualified specialists are on board. There is no one on a strategic missile and the results will be the same, and perhaps even greater, than from missiles fired from a submarine. Why risk an expensive submarine weapon and its entire crew in such a poor cause? We might be asked - why then is the NATO fleet preparing to fire missiles at USSR installations specifically from their submarines? It appears to us that this is explained by the fact that neither the USA nor England at the present time has strategic missiles with the range and, mainly, the accuracy of flight, to justify their being fired from USA bases against all our important installations.

If, nevertheless, our submarine fleet will be assigned the mission of destroying enemy shore and rear area installations, in this case the submarine forces must be organized in a new manner. Individual submarine operations off enemy shores must be dropped, because the enemy anti-submarine defense has become very effective. The strike

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

submarine, or a group of them, must have their own direct underwater protection from enemy submarines; and their own reconnaissance submarines to clear the approach routes and the firing area, which is covered not only by the enemy PLO submarines but also by his mine obstacles and other technical means. Thus, even in this case there is a need for a special large unit of submarines, which we have already mentioned.

In no way by our discussions are we preparing to deprecate the significance of missile strikes from submarines against enemy naval bases or other of his installations. We are discussing only the selection of the most effective, economical, and reliable weapon for the accomplishment of a given mission. It appears to us that with the development and perfection of strategic missiles, missions for the destruction of shore installations by submarines will be eliminated.

The role and significance of first strikes in the initial period of a war have been sufficiently delineated in our military literature. The effectiveness of the first strike depends, first of all, upon the secrecy and timeliness of the deployment of the forces during a threatening period. In a number of military-political circumstances, it will be necessary to carry out such a deployment even during peacetime for, so to speak, protective purposes, without the least violation of existing international practices. Which type of weapon can do this with the most secrecy? Who can covertly occupy positions in the area of probable deployment against us by enemy aircraft carriers and missile submarines, or in the area of appearance of a large convoy with troops? Obviously, only submarine forces can accomplish this, because as we have already indicated, it is a very complicated matter to detect their deployment, to say nothing of determining their exact position and the exact number of submarines in the depths of the ocean and sea.

A few words concerning the supply of submarine forces. Submarine vessels are designated for a long stay under water, which their equipment already guarantees. It is

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

also necessary to provide for the replenishment underwater of certain types of supplies for submarines. Not too long ago the possibility of refueling a jet aircraft traveling at an enormous speed and height seemed unrealistic, yet today this problem has been resolved. Surface vessels already take on fuel from other vessels while underway, as well as while in anchorage, from storage containers hidden in the depths of the sea. Submarines, however, still come to the surface to take on supplies, and in so doing deprive themselves of all their submarine qualities. It is time to create special supply submarines for supplying submarine squadrons underwater and underwater depots from which a submarine could take on supplies while lying on the bottom.

It should be kept in mind that the possibility of counting on stationary surface floating bases is becoming more and more problematical. There is an urgent need for underwater submarine supply bases in bays near our shores or for special submarines to furnish supplies away from bases. The technical solution of this problem is entirely possible.

What kind of deductions can be made from all that has been discussed?

First of all, it appears to us that the appearance of independent submarine operations in naval art is completely natural. The object and goal of these operations will be such that no other types or arms of the armed forces except submarine forces will be able to engage in or achieve them. We have in mind combat with enemy missile-carrying submarines in the Arctic, under the ice, or in the depths of non-freezing oceans and seas, and also, the destruction of underwater and surface communications routes. In the future, submarine operations will be able to achieve operational, as well as strategic, goals.

Submarine operations will also be conducted in those instances when the accomplishment of a mission jointly with aviation, or by aviation alone, is difficult or, for many reasons, temporarily impossible. We are referring to the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

conduct of submarine operations involving the destruction of the carrier strike large unit (AUS) and the destruction of naval bases and the forces stationed there, as well as a number of diversionary operations, including the landing of tactical amphibious forces.

During the conduct of submarine operations with any type of goals, in a number of instances, when it is possible, a joint operation of submarines with various types and arms of the armed forces is not excluded, first of all with the missile troops and aviation; but at the same time it should be remembered that forms of coordinated operations, besides strategic ones, are becoming more and more complex.

In order to support the conduct of submarine operations, it appears to us that it is necessary now to resolve a number of organizational and technical problems:

-first of all, to work out the organization of strike submarine large units (squadrons);

-to organize a system of covert underwater communications and television in order to ensure navigational security of movement in the depths and to maintain position in an underwater formation, as well as to control the large unit during the delivery of strikes against the enemy underwater;

-to create navigational charts especially for the operation of submarine forces at all depths attainable by them (with an indication on the charts of the temperature, density, and transparency of the water, and the relief of the bottom, currents, and other data);

-to work out and create materiel-technical means for underwater navigation (underwater beacons with coded format) in our own as well as in neutral waters; and also, means of obstruction, placed covertly from submarines (light nets in combination with mines);

-to work out a system for all types of underwater supply, for submarines lying on the bottom at points of dispersal

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

and at definite depths and not moving;

-to create a class of special submarine tankers and submarine transports for the shipment of combat supplies, equipment, and contingents of personnel.

None of these proposals is fantastic, for a number of them already are coming into being. The task now consists of creating an orderly system of theoretical postulates and to give clear-cut "orders" to our technology on the basis of these, lest the realities of combat operations of submarines catch us unawares.

In this article we have attempted to present and, wherever possible, to substantiate, certain problematical questions of submarine operations which are subject to detailed elaboration, because submarine forces must, above all, prepare themselves for the conduct of submarine operations as the naval operations of the future.

To Develop the Theory of Soviet Military Art

by

Admiral V. Tributs

The decision of the Minister of Defense, Marshal of the Soviet Union R. Ya. Malinovskiy, on the publication of a Special Collection of Articles of the Journal "Military Thought", in which materials dealing with the most pressing problems of today in the development of the theory of military art will be published, merits a salute. This decision will find wide approval and support from all command personnel of the Soviet Armed Forces.

The development by marshals, generals, and admirals of new military-theoretical problems, and the publication and comprehensive discussion of the corresponding materials, will facilitate the development of Soviet military art and the working out of unified views on the nature and methods of waging armed combat with the use of means of mass destruction, missile weapons, and the newest military equipment.

It must be noted that up to the present time the development in our Armed Forces of the most acute and pressing military-theoretical problems has been of a timid nature. This work, which is very important in content, scope, and rate of execution, is still limited.

As a result of this, for a number of years we have not been able to overcome the gap which has arisen between the level of development of the means of destruction and their delivery vehicles and the theory of military art. The latter obviously lags behind and does not keep up with progress in the area of means of mass destruction, missile weapons, and combat equipment in general.

In developing the theory of military art, we must proceed from a quite clear understanding of the fact that under modern conditions wars will not proceed as in the past.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

They will bear little resemblance to previous wars. In view of this, one should speak not so much of the necessity for revising the theory of military art, which will lead us only to partial solutions, as of a new, revolutionary approach to the development of the most vital military-theoretical problems which have appeared before us in recent years.

Modern armament which permits, in essence, an unlimited increase in the speed and scope of destruction, demands not simply a revision but the fundamental development and creation of a new theory of military art, conforming completely to the potentialities of the latest means of combat. At present it must be developed in conformity first of all with the means of mass destruction and missile weapons, the development of which leads to a radical change in the structure of the armed forces as a whole.

Among modern military problems, one of the most important places undoubtedly belongs to the problems of the situation of threat and the initial period of war. To approach the solution to these problems correctly, it must be quite clearly understood that the situation of threat and the initial period of war are not farfetched, but are completely objective strategic categories. It is impossible, therefore, to agree with those authors who assert that under modern conditions war can begin suddenly and that the situation of threat will not occur at all. Such assertions are patently false. The situation of threat will always occur but its characteristic indicators and duration may be extremely diverse. Specifically, there may also be a variant of the situation of threat when its duration will be very, very short.

However, one cannot even conjecture such helplessness of our military leadership and intelligence in which the direct preparations of the aggressor for surprise attack on our Homeland will not be detected to a certain extent. There exist a significant number of indicators which we must know, consider, and know how to uncover. These indicators will enable one to proclaim in advance the period of threat, accomplish the necessary measures for the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

final completion of preparation for war, bring to complete combat readiness all forces and means for the delivery of immediate and crushing strikes on the aggressor, and also for the organization of defense, protection, and speedy elimination of the consequences of the first strikes.

The threat situation may be characterized by such a status of international relations that as a result of a sharp aggravation of contradictions between the states of the Anglo-American imperialist coalition and countries of the Socialist Camp, the threat of the immediate outbreak of war will become so real that it will be necessary to reorganize the armed forces, the economy, and the entire life of the country quickly in accordance with wartime demands. The situation of threat does not appear at once and its tension will increase in accordance with the aggravation of contradictions, complication of the international situation, and the execution by the aggressor of a series of military, economic, and other measures directed at immediate preparation for military attack. On the eve of the Second World War, the German-Fascist command carried out similar operations over a long period. This complex was to some extent known to the leadership of our country and the military command.

Specific signs of the rise of the situation of threat comprise a complicated number of socio-political, economic, mobilizational, and military measures being executed by the probable enemy with the goal of the immediate unleashing of a war. Not only the birth, but also the nature, of the situation of threat may depend on these measures.

At the present time, for the imperialist states, socio-political measures acquire exceptionally important significance among the various directions of preparation for future war. Characteristic indicators of the birth and development of the situation of threat in this area may be, for example, acute activation of ideological indoctrination of the population, arousing in it a national-chauvinistic and revanchist mood, intensification of propaganda of an alleged military threat from the states of the Socialist Camp, and broadening the activities of various fascist and pro-fascist organizations. To these ends, the enemy will make broad use of radio, television, the press, and various forms of socio-political activity.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

At the same time, active preparation of the population for various types of defense will be carried on.

In the area of economics, there may take place such phenomena as a sharp increase in the rate of output of military industry, expansion of its reserve potential, conversion of enterprises of various branches of industry to intensive fulfilment of military orders, limiting the supplies of raw materials having a strategic significance for enterprises producing articles for civilian consumption, and a number of other measures directed at supporting the development of the armed forces and accelerating the preparation for war. The nature of the ocean and sea transportation of the probable enemy and activities of his merchant fleet will change.

The relatively high readiness of a portion of the forces and means of the probable enemy in peacetime which supports the possibility of sudden initiation of military operations, does not preclude the necessity for him to conduct mobilization, even though it be a partial one. Its basis will obviously be the extensive preparation of the forces and means of the second and subsequent strategic echelons of the armed forces which are impossible to maintain under peacetime conditions. These measures will include the callup from the reserves of enlisted and officer personnel and the intensification of their training, transfers of leading command personnel, dispersal of material-technical stocks, taking military vessels out of storage, mobilizing ships of the merchant fleet, developing mobile shore bases and new bases on the unimproved seacoast, etc.

One of the most important indicators of the situation of threat may be measures of the enemy in preparing his naval forces for specific operations: changing the areas and nature of operational and daily combat training of aircraft carrier large units and missile-carrying submarines, movements of aircraft carriers under the guise of training cruises, training exercises, or movements to bases and ports of states continguous to us, the appearance of aircraft carriers and missile-carrying submarines in zones of ocean

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

and sea theaters of military operations from which they can utilize missile weapons and carrier aircraft against our coast and rear areas of the country.

Significant changes in the nature and setup of military communications, radio counteractions, etc., can be observed. The deployment of forces and means of various types of defense and protection, especially antimissile and antisubmarine ones, will obviously assume wide proportions.

It is especially important to consider that there will occur a significant intensification of all types of intelligence and the activiation of intelligence operations of the enemy with broad use of various technical means. The number of flights of his reconnaissance aircraft and pilotless means of observation, and also violations of our air space will increase. The number of enemy submarines conducting systematic observation of the coast and possibly also the number of violations of our territorial waters by various vessels and ships will increase.

This enumeration of possible indicators which can accompany the beginning and complication of a situation of threat is far from complete (the majority of them, to one degree or another, appeared before the start of the Second World War in 1941). Careful monitoring, study, and comprehensive appraisal of these indicators in their dynamics and interdependence has, for us, very important significance. In this it is necessary to bear in mind that the basic measures executed by the enemy with the aim of preparing for the immediate unleashing of a war will be carefully concealed and conducted with great secrecy.

In view of this, the activity of our intelligence, which in the threatening period must be activated to the maximum extent, gains paramount importance. It must uncover the nature of the enemy's preparations to begin a war and make it possible for us to frustrate all attempts for a sudden attack on our Homeland. The

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

development of modern technical means of intelligence will have decisive significance in the first place to assure effective operations of submarine and air forces against enemy aircraft carrier and missile carrier large units.

Considering the intentions of the probable enemy and his preparation for the sudden and perfidious unleashing of a war, we must orient ourselves to the least favorable variant of the situation, when the duration of the situation of threat will be extraordinarily short.

Considering these conditions, our Navy is faced with a number of difficult requirements:

-the basic forces of the fleet (submarine and aviation) must be continually maintained at the highest level of combat readiness for immediate use of their weapons;

-indispensable stocks of weapons and means of material-technical support must be dispersed and made invulnerable to strikes on them by the enemy beforehand (in peacetime);

-duty forces and means and also forces and means of all types of defense, antiaircraft (PVO), antisubmarine (PLO), antimine (PMO), etc., and protection must be at a high level of readiness for their immediate use;

-efficient organization and method of preparation of missile weapons for their immediate dispatch to large units, units, and vessels, which still requires a significant amount of time, must be worked out beforehand;

-advanced organization and performance, in specific threatened areas of ocean and sea theaters of military operations, of systematic and reliable reconnaissance, with the aim of uncovering first and foremost the nature of the operations and intentions of missile carrier and aircraft carrier forces of the enemy;

-maintenance at a high level of readiness of the means of controlling forces and the entire communication system.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Under modern conditions the initial period of a war acquires extremely great importance. Our entire strategy must be purposefully directed so that in this very period of armed combat we may make maximum utilization of the full might of nuclear and other means of destruction and thoroughly predetermine the fate of the enemy.

The top-priority mission in the initial period of a war must be the frustration of a sudden attack by the enemy and the infliction on him of immediate and crushing strikes with the use of all the latest means of destruction.

The determination of the specific content and duration of initial operations does not enter into our mission. Very many diverse variants may be proposed for this. However, one thing is clear -- that the main content of the combat activities of our armed forces in the initial period of war will consist of missile operations in which missile and strike forces of the fleet missile-carrying submarines and missile aviation will also take part.

The effectiveness and success of combat operations in the initial period of a war, to a great extent, will depend on the degree of understanding of the missions assigned to us and the knowledge of the peculiarities of war under modern conditions. It seems expedient to us to point out that further elaboration of problems of the initial period of a war must lead to the singling out in the theory of military art of a special and relatively independent area - the initial period of a war. This will make it possible to raise to a higher level the elaboration of problems, both of the situation of threat and the initial period of a war.

Without touching on the general and extraordinarily important problem connected with determining the structure of the armed forces, which will be solved under the influence of the new situation, when the basis of their entire striking power even now is the missile troops, we shall attempt to throw light on some questions relating to the Navy.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Undoubtedly the structure of the Navy under the influence of the development of weapons and technology has changed sharply and will change in the future.

Now the basic striking power of the Navy will be composed of submarine forces equipped with missile weapons and long-range torpedoes, and also missile aviation. At particular stages of a war, these strike forces may be strengthened by allocating missile large units from the reserve of the Supreme High Command. The basic composition of the Navy will also include the forces required for protection of the coast and our own sea communications lines. These will be surface vessels equipped with missiles and antisubmarine weapons, and coastal missile units. Finally, the Navy must have special forces required to accomplish the missions of antisubmarine and antimine defense (antisubmarine defense vessels and aviation and minesweepers), intelligence forces (reconnaissance aviation), and a number of other forces.

Not only in a structural but also in a qualitative sense, the modern Navy will radically differ from the Navy of the period of the Second World War and the subsequent years.

We must bear in mind that in a future war we will have to deal with an enemy with a strong Navy, who places great significance on ocean and sea axes with the goal of preparation for and execution of sudden attack by aircraft carrier and missile carrier forces. Therefore, the simplification and narrowing of the missions of the Navy which are going on are premature and completely unjustified measures. On the contrary, under modern conditions the missions of the Navy will become especially critical and more complicated, and the role of the Navy in a future war, if the imperialist aggressors unleash it, will, undoubtedly, grow.

First of all, it is necessary to point out that our Navy will perform missions of an offensive and defensive character in close coordination with the missile troops and other types of armed forces in complete conformity with the unified strategic concept and war plan. Obviously, such missions may be:

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

-destruction of the main aircraft carrier strike large units, missile-carrying submarines and groupings of antisubmarine forces of the enemy;

-frustration and disruption of ocean and sea communications lines by destroying convoys and transports at sea and annihilating naval bases, ports, and economic centers located on the coast;

-supporting our troops in their offensive and defensive operations in coastal areas, in the capture of straits and the coastline in straits zones;

-protection of our own naval communication lines.

The destruction of strike aircraft carrier large units and missile-carrying submarines of the enemy will have paramount significance for the elimination of the threat of strikes launched by the enemy from the direction of the ocean and sea. This is one of the most important missions of the Navy, the fulfilment of which becomes most pressing during the initial period of a war.

The destruction of various coastal objectives, including naval bases and ports, and also the destruction of enemy vessel forces located in them, will be executed by naval forces, both independently, and jointly with the missile troops.

The accomplishment of the enumerated basic missions of the Navy in ocean and sea areas contiguous to the theaters of military operations in Europe will support our troops in the execution of swift offensive operations. At the same time we shall note that in various naval theaters of military operations, depending on the general course of armed combat, other missions of a most diverse character may face the Navy.

In the series of new missions now facing the Navy, it is necessary to single out an especially important mission, which is that we must assimilate missile weapons at an accelerated pace and learn to use them skilfully and

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

effectively from submarines, surface vessels, and aircraft, as well as from the shore. New weapons become a real and formidable force only when they are thoroughly and skilfully mastered by the personnel of the armed forces. This applies in full measure primarily to missile weapons.

At the same time one also cannot underestimate those types of weapons with which we are still armed and which for some time will not lose their combat value. It is natural that we not only do not have the right to lose the skills acquired in their effective utilization but are obliged to improve them continually.

In the article of Colonel-General A. Gastilovich[1] a highly important question is raised connected with an estimate of the possibility for our troops to carry out the defense of the coast against landing forces. However, in our view, these questions did not receive proper elucidation in the article. Its author proceeds from the assumption that in a future war the enemy will not be able, and will not try, to conduct large-scale landing operations with decisive goals, and therefore the author approached the solution of this question of defense against a landing, in what may be called a somewhat oversimplified manner, with which it is in no way possible to agree.

From an analysis of the operational training of the armed forces of the Anglo-American bloc, exercises and maneuvers conducted in recent years, estimates of the nature and direction of construction of naval forces, and from official documents, one is forced to the conclusion that the probable enemy in a future war not only will not reject such an effective form of conducting offensive operations on a strategic scale as large-scale landing operations, with the aim of capturing territories and broadening the front of armed combat, but on the contrary will execute them very widely. The execution of such operations by the enemy is possible even in the initial period of a war. Therefore, one should not be guided by the fact that the enemy will not try to invade the European

---

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

or any remote theater of military operations by means of large forces. Our attention must be directed to the study of the operating methods of the enemy in landing operations and to devising effective methods for counteraction and elimination of his attempts to execute such operations.

Special attention in this must be paid to the study of enemy methods of landing airborne forces, subsequently reinforced by amphibious landing forces.

The postulation of such a mission is, in our view, more correct. Profound and comprehensive knowledge of these questions will make it possible to organize successful combat against enemy landings. It is known that our defense against landing forces is organized and set up basically with forces of the maritime front which are responsible for preventing enemy invasions from the direction of the ocean or sea. The Navy, participating in this defense, fulfils the missions peculiar to it.

From the arguments of Colonel-General A. Gastilovich it follows that the basic strike against the enemy's landing forces, with the aim of routing him, must be launched only after he has landed on the coast. This is a fundamentally false assertion.

At present we already have the potentialities to detect enemy preparations for a large-scale landing operation. In the future these potentialities must be increased by utilizing new technical means. But this is not the only thing which permits us to eliminate successfully the enemy's attempts to execute a large-scale landing operation. The main thing is that missile weapons and the modern development of naval forces offer us wide possibilities for pinpointing enemy landing operations both on his territory and at sea, i.e., before the landing of his troops on our shore.

Thus, the main efforts of defense (operations) against landing forces must be transferred from our shores deep into the enemy's maritime operational zones, into his territory, and into his rear areas where landing operations are prepared and forces designated for participation in them are concentrated.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Defense (operations) against landing forces must be given not a waiting, but an active offensive character. The mission must now consist of not permitting the landing of enemy troops on the sea coast, their consolidation there, and creation of bridgeheads for further advance. This is all the more important as every sea landing operation is accompanied and supported by large-scale airborne landing operations. The destruction of landing forces located at sea, landing and disembarking means at ports and bases, and not permitting landings of enemy troops on the shore, will greatly facilitate the combat activities of our ground troops in offensive and defensive operations on coastal axes.

In his article, Colonel-General A. Gastilovich raises the extraordinarily important question of control. However, this question is not developed, apparently in view of the author's opinion that "from the viewpoint of the substance of control of operations, new forms of armed combat will not bring about fundamental changes". If we consider that the most vital aspect of control, its heart, is the working out and adopting of new solutions, then we shall hardly ever detect any sort of evolution in it, either in the past or the present.

Actually this question is considerably more complex. We think that the opinion of General A. Gastilovich as set forth above does not conform to the objective character of the changes occurring in the entire sphere of control, its principles, substance, organization, methods, and means.

Obviously, it is not by chance that problems of control, especially its automation and the use of electronic computers, is of late in the center of attention of our military-theoretical thought. It seems to us that the substance of control has gone through a definite evolution in the past and at present is undergoing extraordinarily great changes. The most important of these is the fundamental growth of the significance of centralization of control and its concentration in strategic spheres, which is the result of the influence of equipping the armed forces with new means of destruction. One should proceed to the solution of the latest problems in the area of control primarily from this point of view.

Intelligence - to the Level of Modern Tasks[1]

by

Lieutenant-General of Aviation P. Dankevich

Marshal of the Soviet Union V. Chuykov's article is extremely timely and possesses great significance for a further increase in the combat readiness of our troops. The author's suggestions, both organizational and technical, are directed at the further improvement of the forces and means of military intelligence, and they deserve thorough study and rapid practical implementation.

The role of intelligence is understood by everyone; it is one of the basic types of combat and operational support of troops. However, the lag in the development of the forces and means of intelligence, in contrast to the uninterrupted improvement of combat weapons, gives rise to apprehension and anxiety.

The imperfection in the organizational structure of the organs of military intelligence, as well as the weakness of their technical equipment, is correctly noted in the article.

Let us briefly consider the problems of aerial reconnaissance touched on in the article.

Under the conditions of the high maneuverability of weapons of mass destruction and of troops in operational and tactical depth, and the dynamics of modern combat operations, aerial reconnaissance is one of the basic types of intelligence. It is capable of observing large areas and obtaining the most reliable and documentarily supported intelligence data on important enemy objectives in a short period of time.

---

1. Special Collection of Articles of the Journal "Military Thought", First Issue, 1960.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In connection with the increased scope of tasks which are performed by aerial reconnaissance, and the difficulty of their fulfilment, we consider that Marshal of the Soviet Union V. Chuykov is absolutely correct in suggesting that an air army (VA) of a front have one regiment of operational and one regiment of tactical aerial reconnaissance. Furthermore, it is desirable that two squadrons in an operational reconnaissance regiment composed of three squadrons be equipped for night photo-reconnaissance and infrared photography, and in a regiment composed of two squadrons, that one of the squadrons be so equipped. Units of such an organization will be able to detect more reliably all enemy operations carried out during the hours of darkness.

For the immediate determination of the coordinates of mobile targets detected by aerial reconnaissance crews, the RYM system and direction-finding equipment must be widely used. It is therefore desirable to have 6 to 8 aircraft equipped with this system in the composition of an ORAP (separate reconnaissance aviation regiment) of operational reconnaissance.

For the support of combat operations of the missiles of a front, the chief of front artillery must have aerial reconnaissance means at his disposal, for example, an artillery fire adjusting reconnaissance aviation regiment (2 to 3 air squadrons).

There should be a single photogrammetric center in the composition of a regiment for the processing and rectification of aerial photos and the determination from these photos of target coordinates. Such a center will be able to unite the photo specialists of the separate artillery fire-adjusting reconnaissance aviation regiment (otdelnyy korrektirovochno-razvedyvatelnyy aviatsionnyy polk - OKRAP), the artillery photogrammetric batteries, and also the specially trained officers from the topographic service of the military district. The photogrammetric center is the final authority for the processing of photo documents and the issuance of target coordinates to the command.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Non-organic (neshtatnyy) reconnaissance aviation squadrons of air army air divisions will, as a rule, conduct aerial reconnaissance and re-reconnaissance in support of the combat operations of their own large units (soyedineniye).

The time is quite ripe to pose the question of the transfer of the means of aerial radiotechnical reconnaissance from the composition of an air army to a radiotechnical regiment of special designation (osoboye naznacheniye - OSNAZ), subordinate to a front, in order to achieve centralization of control and clarity of purpose in the organization and conduct of such reconnaissance.

Attention and support are deserving for the author's suggestion for the inclusion in the composition of a combined-arms and tank army of an organic regiment of tactical aerial reconnaissance consisting of 2 to 3 squadrons. In our view, a regiment should have one artillery fire-adjusting reconnaissance squadron armed with multi-place aircraft and helicopters for re-reconnaissance and fire adjustment for army missile artillery.

The availability to ground troop armies of their own organic means of aerial reconnaissance will increase the initiative of the commander and the staff of an army in the organization and conduct of combat with the enemy's nuclear weapons and will reduce the time needed for assignment of tasks and for the receipt of reconnaissance data from the crews of reconnaissance aircraft. In order to ensure the timely receipt of reconnaissance data from airborne aircraft (helicopters) and the control of crews in the air, the large units of ground troops must have radio stations (receiving and transmitting) with the necessary anti-jamming features and range of operation (up to 200 km).

In order to fulfil the entire scope of tasks assigned to reconnaissance aviation, the latter must not only be greater numerically in its composition, but it must also be correspondingly better equipped technically.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

A reduction in the combat strength of the aviation of a front, in our view, must not lead to a decrease in the number of reconnaissance aircraft until they are gradually replaced by pilotless means of aerial reconnaissance.

Modern technical outfitting of the means of aerial reconnaissance is most inadequate and obviously lags behind the development of combat weapons. The reconnaissance aircraft presently in use will not be able to provide the full scope of reconnaissance data to our missile and aviation units.

For the successful conduct of aerial reconnaissance, special reconnaissance aircraft are needed, capable of conducting observation from various altitudes (from 100 meters up to 25 to 30 km) and having a great range of speeds (up to 2000 to 2500 km/hour) and sufficient range and duration of flight. It is perfectly obvious that such aircraft must have improved flight and ground technical equipment, enabling them to conduct reconnaissance and photography by day and night from any altitude, to conduct television and radiotechnical reconnaissance, and to rapidly transmit data on the enemy with the use of automatic coding and secure transmission apparatus.

A no-less-important element of strengthening the organs of military intelligence is the training and retention at all echelons of intelligence officer cadres and their acquisition of experience in the organization and conduct of reconnaissance, especially of the weapons of nuclear attack. It is also very important to take stock in peacetime of targets detected on the territory of the probable enemies.

Concerning the urgent necessity for the creation in our armed forces of more sophisticated means of reconnaissance, a number of articles have been published in the military press and many proposals have been put forth at military-scientific conferences; however, the accomplishment of this most important task is moving very slowly.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

The urgent execution of measures directed at the improvement of the organizational structure of military intelligence as a whole, including aerial reconnaissance, and the marked improvement of technical equipment of the means of reconnaissance, undoubtedly will permit the elimination of the lag in the capabilities of intelligence in contrast to the rapid development of combat weapons, and will fully support the combat operations of our troops.

The Problem of Transportation in Modern Warfare

by

Lieutenant-General of Technical Troops I. Kovalev,
Colonel-General of Technical Troops P. Bakarev, and
Colonel K. Pavlovich

The appearance of nuclear/missile weapons has caused basic changes in the means and methods of conducting armed combat.

On the basis of the well-known tenet of Engels that "tactics and strategy depend, first of all, on the level of production and means of communication attained at a given moment" (F. Engels, Anti-Duehring, State Political Publishing House, 1952, page 156), it is necessary to examine in the light of new conditions, one of the problems of utmost importance to our country, namely, the problem of transportation in modern warfare, the strategic role of which has grown immeasurably.

V.I. Lenin indicated that without well-prepared and organized transportation, and without railroads, modern warfare is an empty phrase.

These tenets of Marxist-Leninist teaching retain their full strength and meaning. Modern warfare will demand the maximum effort of the economic, military, and psychological forces of the country. From its very first moments the efforts of all types of transportation must be concentrated on supporting combat operations of the missile troops, PVO troops, and the first strategic echelon of our Armed Forces. At the same time tremendous efforts must be directed at ensuring shipments for mobilization of the armed forces and their strategic concentration.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(

[redacted] 1.3(a)(4)

In connection with this, it is impossible to agree with the opinion of Colonel-General A. Gastilovich which was expressed in his article.[1] He apparently maintains that allegedly mobilization and strategic deployment of a multimillion-man army is impossible and unnecessary under present conditions because nothing from the interior of the country will reach the front in time, and may not even reach it at all. In his opinion, the outcome of war will be decided by missile troops and border district armies, in such strength and with such armament as they had when war fell upon them.

The views of Colonel-General Comrade Gastilovich are apparently based on the assertion that allegedly under modern conditions only "blitzkrieg" war is possible.

We cannot agree with this viewpoint. The country and its armed forces should not be prepared only for a "blitzkrieg" war. The risk is too great, too great and tragic are the possible consequences in the event that the war assumes a protracted character. Indeed, the fate of the Socialist Camp will be placed on the scales of war. Prolonged war must not be rejected at the very outset. On the contrary, it is for just such a war that the country and its armed forces must be prepared, allowing, at the same time, for the possibility of a "blitzkrieg", and preparation for the latter must be provided for and carried out, but within the framework of preparation for a protracted war.

The tasks connected with preparation of transportation for war are distinguished by their tremendous labor-consuming character and demand great resources and attention. To organize these properly there must be a clear and concise conception of the nature of modern warfare. If we agree with the viewpoint of Colonel-General Comrade Gastilovich, and rule out the possibility of anything but a "blitzkrieg" which would be decided by the forces of only border district armies, and plan the development of the war economy, and specifically transportation, accordingly, then we may lose precious time made available by the period of peacetime development, and at a moment of severe trial find ourselves ill-prepared for a protracted war.

---

1. Special Collection of Articles of the Journal "Military Thought", First Issue, 1960.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

Our opinions are based on the fact that nuclear/missile weapons will not eliminate massed armies but, on the contrary, will cause their inevitable increase, because losses in personnel will increase and large numbers of reserves will be required to replace them. Besides, no amount of missiles can ensure the occupation and retention of enemy territory; troops are needed for this, and a great many troops.

The decisiveness of the aims and the tremendous spatial scope of modern warfare make it necessary to transit considerable expanses. Armed combat carried on simultaneously in several isolated theaters of military operations will call for strategic and operational maneuvering of forces and weapons, as well as the bringing up of large quantities of supplies to troops in action during the course of the war. These shipments, for the most part, will be carried out not only on the territory of the USSR, but also on that of the adjacent allied countries, as well as on enemy territory.

Organizing shipments between countries is complicated by the varying widths of railway gauge, differences in means of transportation, and by the absence of a unified controlling organ which has appropriate authority for carrying out and coordinating military shipments between countries, conducted on land, sea, and air.

In addition to military shipments, consideration must be given to the large volume of shipments within each country to satisfy the requirements of the military economy and civilian population of the countries taking part in a war.

* * *

Recently, with the spread of opinion regarding the possibility of a "blitzkrieg", and the simplifications permitted in conducting command-staff exercises, many generals and officers have formed an incorrect idea

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

regarding the place and role of various types of transportation in war. The role of railroads is greatly belittled because of their supposedly great vulnerability to strikes of all types of weapons and the complexity of reconstructing them. These ideas are quite erroneous. Their authors fail to take into consideration the fact that railway transportation remains the basic and decisive type of transportation in the zone of interior and one of its basic types within the limits of the front.

The experience of many wars shows that with a well-organized reconstruction service, railroads possess a high degree of viability, and any damage to them is quickly eliminated. This pertains to the conditions of nuclear/missile war as well, during which it is possible to maintain relatively prompt reconstruction of damaged sections of railroad lines by the assignment of appropriate manpower and the extensive mechanization of work.

In relation to this question, the statements of two prominent American generals are of considerable interest.

The former commander of the 8th U.S. Army in Korea, Van Fleet, writes in his memoirs: "We knew that the basic mass of military supplies was delivered to the enemy by rail. We knew the location of all railway lines. We had superiority at sea and in the air...We did everything possible day after day, and still could not stop the traffic of the Red trains. We attacked with dive bombers and from low altitudes, shelled with artillery fire from heavy sea and landbased guns, attacked with rocket weapons and machine guns, and organized sabotage. We were witnesses of new proof of the dependability and flexibility of railroads in wartime."[1]

Chief Engineer of the U.S. Army General Hall, in mentioning that in case of war railways will pass from the category of a necessary means of transportation to one of vital importance, stresses the fact that even under the impact of the atomic bombs dropped on Hiroshima and Nagasaki, railway installations were the most stable.

---

1. James Van Fleet, Railway Transport and the Winners of Wars. Washington, 1956.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

All this attests to the high viability of railroads and, consequently, also to the fact that with appropriate preparation and organization of a reconstruction service, they will be one of the major strategic means of support for armed combat even in modern warfare.

For proper clarification of the role of the individual types of transportation in the economy of the country, now and in the near future, let us list some figures which characterize their relative proportion in relation to the overall freight turnover of our country.

Types of Transportation	1940	1958	1965
	in percent		
Rail	85.1	81.17	71.33
Sea	4.9	6.6	10.5
River	7.4	5.3	5.1
Pipeline	0.79	2.1	6.8
Motor Vehicle	1.8	4.8	6.2
Air	0.01	0.03	0.07

It is apparent from these figures that rail transport still accounts for more than 80 percent of all freight and passenger shipments, and if we count only that which covers distances of over 1,000 km, then the proportion of rail shipments will rise to 90 to 95 percent. This should always be kept in mind in working out various theoretical conceptions and in developing long-term plans for shipments, so that they are based on the actual capabilities of the transportation means.

It is also necessary to take into consideration the fact that the railway type of transportation is the cheapest, and, after all, questions of economy have important significance not only in peacetime but in wartime as well.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The cost of shipping one kilometer-ton of freight by rail is about 3 kopeeks, as compared to 58 to 70 kopeeks by motor vehicle, and more than 3 rubles by air transport.

For a long time to come railway transport will have a decisive role in serving the transportation needs of the country, in peacetime as well as wartime, especially in long distance shipping of freight.

During the period of the Second World War, 1941 to 1945, the proportion for the various types of transportation in the total volume of military shipments (excluding medical shipments) were:[1]

Types of Transportation	Average Shipping Distance (km)	Proportion (in percent)
Railway	700	70.5
Water (sea and river)	700	9.5
Motor Vehicle	100	19.8
Air	700	0.2

In modern offensive operations, when the operational rear is of considerable depth, regardless of the development of other means of delivery, rail transport will carry up to 50 percent of all front shipments. Neither transport aviation, field pipelines, nor motor vehicle transport can replace railways in the near future.

We are for the comprehensive utilization of all types of transportation because no single type can independently fulfil all the needs of the national economy and the armed forces. Consequently, the task consists of working out the principles of comprehensive utilization of all types of transportation on the basis of a thorough analysis of the nature of modern warfare and taking into consideration the actual potentialities of the theaters of military operations. In accordance with this, we must bring about their development and essential construction.

* * *

1. Military Communications in Light of the Further Development of Military Art. Military Publishing House /date and page missing/

[redacted]

1.3(a)(4)

1.3(a)(4)

[redacted] 1.3(a)(4)

The viability of the transportation network depends to a large extent on the degree of its preparation in peacetime.

One of the most important measures is the development of a network of railroads and highways, construction of airfields, pipelines, river and seaports, and also of bypasses of major junctions of communications lines, tunnels, large bridges, etc. The accomplishment of these tasks will take a prolonged period of time and large capital investments, and in this connection, they must be closely coordinated with the economic needs of the country. It is necessary to combine correctly the economic and defense interests of the country, which in our opinion, is not always done in practice in questions of the development of the transportation network.

For instance, the Seven-Year Plan calls for laying 90,000 km of rails on railroad lines. Of this amount, only 9,000 km are allotted for new railway construction, and the rest will be used for the reconstruction of existing lines and replacement of old rails. It must be stated, that in the course of the past several years the rate of railway expansion has fallen behind the growth rate of the volume of industrial output. For the past 10 years the volume of industrial output has grown yearly by 10 to 12 percent, but the expansion of rail lines has been only 1 percent, and highways even less than that. The density of the network of rail lines and mobile highways even in the western theater of military operations, the most favorable in this respect, is illustrated by the following figures:

	Rail lines	Automobile highways
	(in km per 100 sq km of territory)	
In the Soviet Union	2.7	10.5
In other countries of the Socialist Camp	9.2	42.0
In the capitalist countries	10.7	75.0

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

It is necessary to note that in compiling these figures on the USSR, only those territories having the most highly developed networks of railways and automobile highways were considered.

Having a total network of main railway lines stretching for 123,000 km, we haul 60 percent more freight than the entire railway network of the USA, which stretches for 340,000 km (first-class roads only). Thus, the density of freight traffic carried by railways in the USSR is 4.5 times that of the USA. During the current Seven-Year Plan the average freight traffic density will be increased by another 50 percent approximately. Thus, despite the development of other means of transportation, the operating pace of the railways of the USSR in the coming years will not decrease, but on the contrary, will increase considerably. Meanwhile, it is now planned to utilize basic capital investment not for the development of new rail lines, but for the reconstruction of existing lines.

From the military viewpoint, in a number of important areas it would be more correct to solve the problem of ensuring the shipment of the increasing flow of freight by building new railway lines, because a denser network also has a higher degree of viability.

Converting the basic railway main lines to electric traction will not raise the viability of the transportation network, because the work of the railways will depend entirely on the uninterrupted performance of the powerful electric power plants, which in themselves will be an important target for enemy strikes. In these circumstances it is necessary to establish alternate sources of power (zakoltsevat) in our power system as soon as possible.

Diesel-electric traction is more independent, and consequently more viable, provided that stocks of diesel fuel are established for a prolonged period of time, because fuel suitable for diesel locomotive use is produced in only one or two places in the country. It must also be noted that our main line locomotives cannot be used abroad because of their clearance and load characteristics and the design of the running gear, which is not adaptable to West European gauge.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

One of the measures for increasing the viability of the transportation network which is being carried out in peacetime is the construction of bypasses of major railway junctions and establishment of stocks of reconstruction materials and structures.

In our opinion, a number of errors are committed in this matter. Bypasses of junctions take a long time to build, and are expected to be used only in wartime. Thus, large capital investments are immobilized. For example, the bypass of the Smolensk railway junction, which has been under construction for 10 years, and whose estimated cost is 52 million rubles, does not completely perform the task of increasing the viability of this railway. It is necessary to construct wide bypasses of junctions, taking into account the possibility of using them in peacetime for transporting local freight, thus allowing for fast recovery of the expenditures which have been made.

Little attention has been given to the problems of the construction and development of rail spurs to river and seaports, moorages for support of combined rail-water shipments, and also to the construction of railway spurs to airports.

Not everything is going well in establishing stocks of materiel, structures and equipment for the reconstruction of bridges, tunnels, ports, airfields and other installations in the transportation network. For instance, the Ministry of Transportation is stockpiling pre-assembled, transportable (tselnoperevozimyy) spans weighing up to 68 tons to reconstruct bridges, and they can be transported only by rail and installed by special railway cantilever cranes.

Under modern conditions, when the enemy will attempt to cut our railway network into individual isolated sections, in a majority of cases it will not be possible to transport these spans and cranes by rail to the bridges under reconstruction.

In our opinion it would be proper to stockpile prefabricated bridge structures, and cranes to install them, so that in case of need they could be shipped by motor vehicle transport.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

It is advisable also to establish stocks of materials and structures for reconstructing highway bridges and river ports.

At present the need has arisen for closer coordination of activities among the member countries of the Warsaw Pact. Many problems have accumulated which require coordinated solutions and collaboration. Specifically awaiting a solution are problems of great importance such as:

-establishing a park of special rolling stock which would allow for automatic transfer (while in motion) from the Soviet gauge of 1524 mm to the West European gauge of 1435 mm and back again without changing trucks;

-setting up extensions of rail lines with Soviet gauge deep into the territory of Poland, Hungary, Czechoslovakia and Rumania and of West European gauge deep into our territory;

-establishing common bases for reconstruction materials and structures and consolidating them;

-reinforcing railway and highway bridges to meet the load specifications of our rolling stock and units of independently driven equipment.

All these problems have a direct bearing on ensuring the viability and the uninterrupted performance of the transportation network during a period of war.

To solve them we must first of all enlist the services of the already existing Organization for the Cooperation of Railroads of the Socialist Countries (Organizatsiya Sotrudnichestva Zheleznykh Dorog-OSZhD) but include in it appropriate military specialists.

* * *

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

In addition to engineer-construction measures, the viability of communications lines is ensured by the presence of reconstruction organizations, capable of moving quickly to work installations and having at their disposal the necessary equipment cadres of specialists trained in working under conditions of radioactive contamination of the terrain.

Within the boundaries of the zone of the front, the viability and reconstruction of communications lines will be ensured by railway, engineer, and road units which are trained to perform this work in peacetime.

Reconstruction of the rear area networks is entrusted to the organizations in charge of their operation and which do not have the technical equipment or the trained cadres for performing this work.

The exception is the Ministry of Transportation, which has reconstruction trains and bases of reconstruction materials. In addition, for reconstruction of major installations it is provided that construction organizations of the Ministry of Transport Construction will be called upon. However, even these organizations are not trained in the reconstruction of installations destroyed by nuclear weapons.

In case of large-scale destruction of major railway installations whose reconstruction will require a great deal of time, the organization of temporary transshipment areas (vremennyy peregruzochnyy rayon - VPR) should be provided for in order to transit obstructed areas by using other forms of transport, primarily motor vehicle. For servicing the VPR, special mobile formations should be organized for wartime and equipped with loading-unloading machinery and motor vehicle transport.

It would be incorrect to assume that such special formations will be able to perform independently the task of transshipping freight in obstructed areas. Even rough estimates indicate that for setting up a VPR on such a main line as that between Moscow and Minsk, when the railway

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

junction at Vyazma has been destroyed, and through which pass 76 pairs of trains daily, the transshipment area stretches for 250 to 300 km, and for it to service transshipment of supply trains alone we shall need no less than 10,000 motor vehicles and more than 15,000 men for the loading-unloading operations.

In circumstances when the enemy inflicts large-scale destruction, it will be very difficult to effect necessary national economic and military shipments without strict centralization of the comprehensive utilization of all forms of transport.

At the present time in our country, all forms of transportation are controlled by various ministries and departments. Some of them are subordinate to central, and some to republic and local organs of authority. Because of this, it is very complicated,even in peacetime, to organize and conduct combined shipments with the participation of 2 to 3 types of transport.

In time of war, such bureaucratic disunity in transportation means is intolerable because it can lead to serious consequences for the armed forces, as well as for the economy of the country, and these consequences would be difficult to correct.

All forms of transportation which are at the disposal of the country can be systematically and expediently utilized only if the control of their exploitation emanates from a single center, closely connected to the Supreme High Command.

In our opinion, it is extremely essential to unite the management of all types of transport in one organ, for instance, in a specially established transportation committee. At the same time, decentralization of control must be ensured by establishing 8 to 10 directing bodies territorially and administratively linked with industrial-economic areas and military districts. Such a system will ensure the viability of the controlling organs and will permit a more effective solution of the problem of combined utilization of all types of transportation in peace and wartime.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

At the same time it is necessary to complete the unification within the Ministry of Transport Construction of all construction organizations which conduct construction of rail lines and highways, pipelines, airfields, and sea and river ports, after preparing them organizationally and technically for wartime accomplishment of the most complex work in reconstructing communications lines in the zone of interior.

However, the forces of the construction organizations of the Ministry of Transport Construction alone will be far from sufficient to reach this goal. Appropriate preparation is needed so that reconstruction work and the establishment of VPR's are also assigned to local territorial organizations and the populace.

In wartime, reconstruction of communications lines in the zone of interior must become a common task of all the people and be organized by the State. People and equipment must be assigned in advance to all the most important installations (rail centers, ports, large bridges, etc.) and, in case of need, must go immediately to the installation and put themselves at the disposal of the chief in charge of organizing the reconstruction work.

Under peacetime conditions, it is expedient to conduct a series of measures in accordance with the policy of the Ministry of Defense and the civilian ministries to ensure more effective utilization of the means of transport in the initial period of a war.

In the present situation, to outfit one fully mobilized motorized-rifle division, various types of equipment must be brought from 29 to 32 separate depots to the activation point from distances of 500 to 2500 km. In order to decrease this volume of shipments at a time when the railways are working under the most strain, complete depots should be set up at the mobilization points, from which all the requisite military equipment and materiel could be obtained at once.

The problem of supplier and consumer routing of trains must be solved in order to reduce to a minimum the layover time of military goods at points where trains are reconstituted.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

It is time to take practical action in creating special freight containers, pallets (poddon) and other means for shipping military goods which will ensure mechanization of loading-unloading work and will sharply reduce the layover time of trains in transshipment areas.

To decrease the time needed for full mobilization and shipment of troops of the first strategic echelon, the traveling speed of trains should be increased to 1000 km per 24-hour period (i.e. doubled) and the weight of a military train increased to at least 1500 tons (gross weight) instead of the 1200 tons used presently. The present level of technical equipment of railway transport fully allows implementation of these measures.

According to modern views, it is planned to reconstruct, in a frontal zone, 2 or 3 frontal railway routes and 1 or 2 lateral ones. To carry out these tasks, the composition of the front includes 5 or 6 railway brigades, reinforced with bridge regiments, battalions of railway pontoon bridges, special formations, and, when necessary, tunnel battalions.

The rate of reconstruction of railways will depend to a considerable extent on the extent and nature of their destruction and on the number of railway units assigned to the reconstruction of one or another railway route.

It is known that in previous wars each of the opposing sides tried to effect complete destruction of railways during a retreat. Roadbeds, tracks, all bridges and pipes, communication lines, railway water supply installations, and service and technical buildings were all blown up. Practically speaking, such complete destruction was possible only in a tactical zone of defense to a depth of 20 to 40 km from the main line of resistance, and then only under conditions of a slow retreat. In an operational zone 100 to 200 km in depth, railways suffered a slight to average amount of destruction.

In the currently effective regulations and instructions of our probable enemies, there is provision by way of "delaying operations" for massive obstructions along communications routes. In the field manual of the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

US Army, Obstruction and Destruction, it is planned to use nuclear weapons to create obstructions. Considerable work has been done in West Germany in preparing structures for destruction. According to available data, mine devices have been installed in more than 300 installations (bridges, tunnels, dams, reservoirs).

The experience of the last war showed that the faster the rate of offensives of troops, the less time the enemy has to set up obstructions. Under modern conditions, with the fast rate of offensive and the dense railway network in the western theater of military operations, it is to be expected that the enemy will be in a position to destroy railways only by individual focal points, striving to split and break up the entire network into isolated sections. Moreover, first to be destroyed will be all large bridges and tunnels. The extent of destruction to railways in this case will not be as great as in the case of complete destruction, but the nature of destruction and conditions of reconstruction will be more complex than in the last war.

Under the conditions of highly mobile modern warfare, when offensive operations are conducted in great depth and the destruction of railways is accomplished at certain points, railway units will have to work along a wide front, separated from each other, as a rule, in small subunits, often in a "deep envelopment" of railway sectors still occupied by the enemy, or in "corridors" made by our troops.

Taking into account the possible tempos of offensive operations, railway troops must reconstruct the basic front railway main lines at a pace of no less than 45 to 50 km per 24-hour period and strive to raise this to 55 to 60 km per day. In the last war the railway reconstruction rate in one front operation was 5 to 8 km on one route (in individual cases up to 20 to 25 km).

In order not to be separated from the advancing troops by more than a distance of a day's ride by motor vehicle transport, railway troops must reconstruct any destroyed point or any installation in 3 to 3.5 days. If its

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

reconstruction requires more time (for instance, building a bypass of a railway junction or bridge, reconstruction of tunnels, etc), then it will be necessary to overcome the obstructed area by establishing a VPR and by wide use of other types of transport.

The task of increasing the rate of reconstruction of railways to 55 to 60 km per day, and more, demands a fundamental change in the technical equipment of railway troops, the creation of new types of reconstruction means based on wide use of automation, telemechanics, and the overall mechanization of reconstruction processes.

Railway troops must be mobile. Their technical equipment and reconstruction equipment must be capable of being transported not only by rail and motor vehicle transport, but also by airplanes and helicopters. Only by this approach can the task of increasing the pace of railway reconstruction to the required level be performed. In addition we must not lose sight either of certain problems of an organizational nature.

As is known, the composition of the troops of the Soviet Army which are deployed beyond the western national borders of the USSR does not include railway units. In case of war, railway units will take at least 5 to 6 days to arrive at the front and start work, while during this time the advancing troops will move forward considerably. Consequently, in the very first days of a war, a significant separation may develop between operating railways and the advancing troops.

All bases for reconstruction materials and structures are also located on the territory of the USSR, at a distance of more than 2000 to 3000 km from the line of deployment of troops of the first line. Even if there are sufficient stocks of these materials, it is impossible to deliver them quickly to reconstruction sites.

Such a situation cannot be considered normal. In order to reconstruct railways in the wake of the advancing troops, railway units and materiel bases must be located as close as possible to departure lines.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

There is no clarity in the problems of organizing the operation of reconstructed sectors and their technical concealment. Many independently operating organizations have appeared in front railway sectors. Reconstruction of railways is conducted by railway brigades and special reconstruction formations subordinate to the chief of railway troops of the front (NZhVF), and operation of the reconstructed railway sectors is ensured by operating railway regiments and operating special formations, subordinate to the chief of the military-operating directorate of the front (nach. VEU). The organization of military shipments is conducted by the chief of military transport of the front (nachalnik VOSO). They all have equal rights and, with the exception of the chief of VOSO, are directly subordinate to the commander of the front. The NZhVF and VEU for special service are also subordinate to the Ministry of Transportation of the USSR.

When our troops are operating on the territory of allies, it must be taken into account that there are also local governmental organs of railway administration with whom the work must be coordinated.

As was pointed out earlier, under modern conditions we must strive for the comprehensive utilization of all types of transportation located within the limits of the front: rail, water, motor vehicle, air, and pipeline. Yet, all these types of transportation are subordinate to different arms of troops and services.

The need has arisen to examine the problem of setting up within the composition of the front a single military transport service (directorate), endowed with the necessary powers for organizing centralized utilization of all types of transportation subordinate to the front and appropriate authority to coordinate problems of military shipments with appropriate ministries and departments. The complement of this directorate must include experienced specialists and representatives of all types of transportation who are capable of establishing and efficiently directing a powerful transport service.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

At the beginning of the Second World War an attempt was made to assign the responsibility for reconstruction and operation of front railways to a representative of the NKPS (Narodnyy Komissariat Putey Soobshcheniya - Peoples' Commissariat of Transportation), who was attached to the Military Council of a front. The experience of many wars has shown that front railways must be controlled by the military, especially beyond the limits of our national boundaries. In time of war, neither railwaymen nor local agencies of authority will recognize anyone else's authority, and no one else will have adequate legal rights.

At the present time the planning of shipments and coordination of the tasks of all types of transportation are the responsibility of the third department of the headquarters of the rear services of a front. This department will be unable to resolve a single practical problem, and will be a superfluous echelon of command, tying up the operations of all transportation agencies. This conclusion is corroborated by the experience of many practical exercises.

To ensure comprehensive utilization of all types of transportation, it will be necessary to make up mutually coordinated schedules and plans (possibly using electronic computing machines), a unified dispatcher control for shipments, good and accurately operating communications, etc. All this requires highly qualified specialists who have experience in working in transportation agencies.

To coordinate the preparation of the entire transportation network for operation in wartime, and also to resolve problems of its utilization in the interests of operating troops, it is necessary to set up, within the scope of the member-countries of the Warsaw Pact, an appropriate transportation agency which must be closely connected with the OSZhD.

It is also expedient to distribute properly the stocks of reconstruction materiel, and to unify reconstruction

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

equipment and reconstruction units so that they will meet modern requirements. Comprehensive utilization of all types of transportation must also be organized in accordance with a unified plan, regardless of the nation to which they belong.

It is perfectly obvious that appropriate preparation of means of transportation for work under conditions of war must be carried out in advance. Every delay in this matter is very dangerous because the scope of the work is so great that it will be impossible to make up lost time in the course of a war.

[redacted] 1.3(a)(4)

Rear Services Support of Missile Troops in an Offensive Operation of a Front

by

Lieutenant-General M. Novikov

Nuclear weapons, missiles of various designations, and radio-electronic equipment are the basis of the further development of our Armed Forces. These means of combat, together with the mechanization of the Army and Navy, have altered the appearance of our Armed Forces and have given them new combat qualities.

In the troop composition of the Soviet Army there are large units and units armed with ballistic, antiaircraft, and other missiles of various designations. A front can have several missile large units and units of front and army subordination, armed with operational-tactical and antiaircraft missiles, and also subunits of tactical and antiaircraft missiles which are organizationally a part of the motorized-rifle and tank divisions.

The extensive equipping of troops with missile weapons and their leading role in the attainment of the goals of an operation bring forward completely new and very responsible tasks for the rear services, namely, the rear area support of missile troops. The fulfillment of this task is complicated by the fact that the demands of the front for missiles and missile fuel for an operation attain quite imposing dimensions. According to experience gained from exercises conducted, the expenditure of all types of missiles in an operation consisted of several thousand missiles, while the expenditure of missile fuel was several thousand tons, of which up to 70 percent were oxidizers--components of missile fuel which are extraordinarily dangerous during storage and transport.

It should be emphasized that the success of modern operations will now depend largely upon the uninterrupted delivery to the troops

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

of missiles, nuclear ammunition, and missile fuel, and also upon the timely assembly and preparation of missiles for firing. Therefore, the problems of rear area support of missile troops acquire exceptionally important significance.

As is generally known, primary and alternate siting areas are assigned to missile large units and units in a front offensive operation. They are located along the entire front zone and are echeloned to a great depth. The movement of missile units and large units in the course of an operation takes place, as a rule, by battalion or by battery, at various times, taking into consideration the tasks being fulfilled and the tempos of the troop offensive. The troop missile subunits move, for example, several times in a 24-hour period with jumps of 10 to 15 kilometers, army subunits once in a 24-hour period, and front subunits two or three times during the entire operation. Strictly on the basis of the features of dispersed disposition of missile units and the necessity of their frequent movement, it is necessary to organize the rear services and carry out rear area support of missile troops.

In organizing rear area support for missile large units and units, it is also necessary to bear in mind that missiles, as regards their construction, weight, and overall dimensional characteristics, differ substantially from other types of ammunition, and their preparation for launching is involved with the execution of a number of preliminary tasks with regard to assembly, fueling, and testing. In connection with the great weight and overall dimensions of missiles, specially equipped rail, motor vehicle, and air transport, and also loading-unloading equipment with great hoisting capacity, are required for their transport.

The complexity of supplying the missile troops with missile fuel is explained by its special properties: toxic, aggressive, and hygroscopic. This makes it necessary to have special means of transportation, storage, and pumping of fuel. At the same time, the handling of missiles, special charges, and missile fuel requires an exceptionally high degree of training of personnel of rear services units and installations.

* * *

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It is quite understandable that the high combat readiness of the missile troops is ensured largely by a stable and sufficiently flexible system of supply. However, until recently, a fairly protracted period of probing and experimentation could be observed in this question. Thus, in accordance with existing procedure for assembly and preparation of missiles for firing, the following system of supply for missile troops was provided. It was proposed to have subunits for storage, servicing, and transport of missiles and special charges, and also workshops for the assembly of nuclear warheads, under the jurisdiction of the chief of front artillery armament. The missiles arriving at the front were unloaded at railroad stations and were delivered by motor vehicle transport of these subunits to front depots, and then to supply points, deployed in the axes of operations of the missile large units and units. From here, the missiles were brought by motor vehicle transport of the missile troops directly to their technical subunits, where the assembly, fueling, and preparation of the missiles for launching took place. Besides railroad and motor vehicle transport, it was also planned to use air transport for the transport of missiles and nuclear warheads.

For the supply of missile fuel to the missile troops at the front, there were dumps at the forward and rear area bases of the front. The transport of missile fuel from the rear area to the forward depots was carried out by rail transport or by motor vehicle transport (in case of disruption of the work of railroads). From the forward depots or from their sections, deployed over the terrain in the course of the operation, the missile fuel was delivered by the transport means of engineer battalions and antiaircraft missile units directly to their technical subunits.

As the experience of exercises showed, this system had substantial deficiencies. First, in connection with the fact that the assembly and preparation of missiles for firing--a process that is quite labor-consuming and requires the expenditure of large forces and means, the fulfillment of such tasks is very difficult./one or two words missing/ of units and large units. Secondly, three persons essentially were responsible for the delivery of missiles to the same level of supply: the deputy commander of troops of the front for rear services (rail and air transport), the chief of front

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

artillery armament (motor vehicle transport to the supply points), and the commanding officers of the units(motor vehicle transport to the technical subunits). Thirdly, the missile units broke off contact with the supply points and depots in the course of the operation which led to great strain in the work of missile unit transport. Besides, the system of support outlined greatly complicated the organization of coordination, communications, and rear area control, especially with regard to questions concerning the use of various types of transport for the delivery of missiles, special charges, and missile fuel. The complexity of coordinating these matters adversely affected the efficacy of the work of rear area units and establishments. Cases were noted during exercises, when missiles and missile fuel were delivered to the units at various times, which, in essence, did not ensure the timely combat readiness of the missile troops.

Later, as missiles were improved, the possibility arose of carrying out the assembly and preparation of missiles--not in the technical subunits of missile units, as was done earlier, but in the rear area of the front. This circumstance made it possible, by a number of organizational measures, to improve the entire system of rear area support of missile troops. Technical subunits for the assembly of missiles, and also subunits for the storage and transport of them to the missile units and large units, were introduced into the composition of the front rear area. For convenience of operation, these subunits were integrated into missile technical bases, taking into consideration the specific peculiarities of the employment and preparation of operational-tactical (tactical) and antiaircraft missiles. While the former are used mainly with special charges, the latter are used mainly with conventional charges. Thus, there are two bases at the front: one for the preparation of operational-tactical and tactical missiles (surface-to-surface class), and the other for the preparation of antiaircraft missiles. These bases, depending on the plan of the operation, the tasks to be fulfilled, and the grouping of missile troops, are placed 200 to 250 kilometers from the front line, beyond the range of fire of the main body of enemy missile weapons. Sections, which are deployed on the basic axes of operations of missile units, at a distance of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

100 to 120 kilometers from the front line, are detached from the missile-technical bases. Besides, the missile units of the front, located near missile-technical bases, will obtain everything necessary from them, and the missile large units and units of army and front subordination, moved to the border of the army rear area, will obtain everything necessary from the sections of these bases. Besides the missile-technical bases, the front has at its disposal missile fuel dumps which are able to detach their own sections over the terrain.

There are sub-units for storage and transport of prepared missiles in the composition of the rear services of combined-arms and tank armies. These subunits are placed at a distance of 40 to 50 kilometers from the front line and are moved in the course of the operation in accordance with the movement of missile units and subunits. Subunits for checking out, storage, and transport of missiles prepared for firing must also be in the composition of missile units and large units.

With the given composition and manner of deployment of rear services units and installations, it is envisaged to carry out rear area support of missile troops in the following manner (sketches 1 and 2). Missiles arriving at the front are unloaded at unloading stations (airfields) and are delivered to missile-technical bases (their sections) where the assembly, checkout, and fueling of missiles are carried out. From here, the missiles prepared for firing are delivered by front, army, and troop transport to missile units and large units of front suborindation, and also to armies. From army subunits the missiles are delivered to missile units (large units) and to the divisions. The delivery of missile fuel is carried out from the front dumps directly to the technical subunits of bases and their sections.

1.3(a)(4)

It can be considered that the existing system of supply has a number of advantages in comparison with the former. Missile units and large units, released from a number of labor-consuming functions, become more mobile and maneuverable and their commanding officers can, in connection with this, give more attention to questions of combat use of missiles. The possibility of dispersing the stocks of missiles and missile fuel has emerged.

At the same time, as has been shown by the experience of exercises, the system of supplying missile troops still has rather considerable shortcomings and requires further improvement. This, first of all, concerns such important aspects of rear area work as the organization of transport of missiles, special charges, and missile fuels, and also the planning of missile troop supply. In essence, the organization of transport and the procedure of planning supply remained unchanged after the reorganization of the rear services of the front and army that has taken place in the interests of missile troop support. We consider that all the prerequisites for the introduction of a new, more advanced principle of planning and transport of everything necessary to the missile troops are present.

First of all, let us examine how the matter stands in regard to the transport of missiles, special charges, and missile fuel. In accordance with the existing system, the chief of the front (army) artillery armament is responsible for the organization of the transport of missiles and special charges by all types of transport, while the deputy commander of the rear services is responsible for the transport of missile fuel. In our opinion, such a method of organization of transport will not ensure the timely transport of missiles, special charges, and missile fuel to the troops. The point is that the chief of artillery armament of the front, having at his disposal, for the delivery of missiles, only special automotive transport, cannot use for these purposes all the other types of transport which are not under his jurisdiction. Uninterrupted transport of missiles, special charges, missile fuel, and other important types of materiel supplies to the troops during operations carried out at a great depth, at high speeds, with sharp and frequent changes in the operational

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

situation, and under conditions of heavy enemy action against communications routes and rear services installations, is possible only with the combined use of railroad, motor vehicle, and air transport. Therefore, in our opinion, the deputy troop commander of the front (army) for rear services must have full responsibility for the organization of transport; on the basis of the decision of the troop commander, he will be able to organize the planning of transport and the coordinated operation of the various types of transport taking into consideration the operational-rear area situations which arise. The rear services staff must ensure the direct supervision of the work of special motor vehicle transport units for transport of missiles and missile fuel, and of railroad and air transport, in combination with the directorates of artillery armament, fuel supply, and other services of the front; only by the coordination of their work will the timely delivery of missiles, special charges, and missile fuel to the troops be ensured. With this goal, the deputy troop commander of front (army) for rear services and the staffs of the rear services must organize close coordination of artillery armament and fuel supply services, coordinate plans for the delivery of missiles and missile fuel with the work of the various types of transport, and determine measures for the preparation of a road net and for control of traffic on the roads.

Mostly railroad and motor vehicle transport are used for the delivery of missiles and missile fuel during the preparation of an operation. Missiles, special charges, and missile fuel should be delivered to front missile-technical bases and dumps of missile fuel or to their sections by railroad. Depending on the distance of army rear services units and missile troops from front bases and depots, motor vehicle transport of a front, armies, and missile units and large units can be used for the delivery of missiles to the troops. In the event of disruption of the work of the front's railroads, it is necessary to provide for the duplication of transport by the special automotive transport of the front and for special charges also by air transport. In the course of the operation, the transport of missiles and missile fuel basically must be carried out by front motor vehicle and air transport. Special motor vehicle transport of armies and missile brigades should be used mainly for the delivery

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

of missiles prepared for firing to the units or directly to the firing positions. In the event of long extension of communication lines, it is necessary to deploy depot and base sections on the basis that their distance from missile large units (units) and the army rear areas, does not exceed 50 to 100 kilometers. With a short distance of separation, the transport of missiles from the deployed base sections can be carried out by front, army and troop motor vehicle transport.

* * *

In modern operations, uninterrupted support of missile troops will depend to a significant degree on the availability of stocks of missiles and missile fuel at the front. Inasmuch as missile weapons will be the decisive means for the attainment of the goals of the operation, we believe that the stocks of missiles and fuel for them at the front must be established at the beginning of the operation, calculated so as to provide the complete needs for the entire operation. These stocks should be echeloned and maintained at all levels where missile troops are employed. It is necessary to take into consideration that the greatest quantity of missiles is expended during the first days of an operation. Therefore, in our opinion, not less than 50 percent of all missile stocks must be located in missile units and large units, 15 to 20 percent in the army rear area, and the rest in the front rear area. Owing to this principle of echelonment, stocks can be moved closer to the troops, make the entire supply system more stable and reliable, and thus afford the commander of the front (army) troops and the commanding officers of combined-arms and missile large units and units the opportunity to render timely influence on the course of a battle and an operation. In the echelonment of missile stocks, it should also be taken into account that in the zone of the front offensive there will be created not one, but several groupings of missile troops, varying in their composition and designation, separated from one another by significant distances. Therefore, it is advisable to establish larger stocks on the axis where the main missile troop grouping is operating.

[redacted] 1.3(a)(4

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

For the uninterrupted support of missile troops, it is very important to execute, in good time, maneuver of the stocks. With this goal, units and installations intended for storage of missiles and missile fuel, especially in the troops and armies, must be completely mobile. Missiles must be stored on special carriers (telezhka) (semi-trailers-polupritsep), and missile fuel in fueling vehicles and special tank truck - semi-trailers. In the course of an operation, the stocks of missiles and missile fuel must be constantly replenished. In any case, it is always necessary to have mobile stocks for the troops within the limits of the established norms which will ensure their constant combat readiness.

Correct placement and relocation of rear services units and installations intended for rear area support of missile troops, the organization of their safeguarding, protection, preparation, and employment of railroads and military-motor vehicle roads for the transport of missiles and missile fuel, and also other questions regarding the support of missile troops, can be resolved successfully only with coordinated work of the various services and with unified, centralized control of the rear area. We believe that the rear area support of missile troops is one of the most important measures in the general system of work of the operational rear area. The deputy commander of the front (army) troops for rear services must be one of the basic organizers of rear area support of missile troops.

Some mention should be made of the support of missile subunits of motorized-rifle and tank divisions. Combat operations of these large units proceed at high speeds, with sharp and frequent changes in the situation. The separation of missile subunits included in their composition from army support units, as shown by experience of exercises, may be 70 to 100 kilometers. Under these conditions, it is doubtful that the army, with only its own means, will be able to support the missile subunits of the division in a timely manner. Therefore, small mobile subunits for storage and transport of missiles must be put into the composition of the rear services of the motorized-rifle and tank division.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Uninterrupted delivery of missiles and missile fuel to the troops by motor vehicle transport depends in many ways on the organization of road support. As experience of exercises has shown, front (army) military-motor vehicle roads prepared for the movement of motor vehicle transport with ordinary freight, basically ensures the passage of motor vehicle columns and echelons with missiles and missile fuel. The volume of shipments by this method of supply constitutes up to 500 vehicles in a twenty-four hour period, and usually does not have substantial influence on the intensity of the movement. Therefore, the delivery of missiles and missile fuel must be carried out, as a rule, on the operating net of military-motor vehicle and controlled roads of the front and armies. It is only necessary that the technical standards of these road (the width of the roadway, the grades, the radii of curves, and also the load capacity of bridges) meet the conditions for the passage of special heavy-duty motor vehicle convoys with missiles. It is necessary for the front (army) road unit forces prepare approaches from the basic military-motor vehicle roads to the rear services units and installations of the missile troops and armies, and also to the missile fuel bases and dumps of the front.

One of the basic missions of the road service will be the organization of uninterrupted traffic and top-priority transit of transport echelons with missiles and missile fuel. The transport of missiles and missile fuel most frequently will be carried out by comparatively small columns and road subunits must be assigned for their escort and ensuring their unhindered passage on the roads, especially the overcoming of various obstructed places.

Special attention is now being given to the medical support of missile troops. This follows from specific conditions of their disposition in the front zone and the work of the personnel with nuclear ammunition and missile fuel. One of the essential features in the work of the medical service of missile units and large units is the necessity to conduct a gamut of measures directed at preventing the contamination of personnel by ionized radiation and by the components of missile fuel. The measures must provide for the execution of control over the work conditions of the personnel during

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

the handling of nuclear warheads and missile fuel, and also for the rendering of necessary medical assistance.

It is very important to determine correctly and establish the procedure for planning supply of missile troops. It was carried out in different ways during the exercises conducted. For example, during one of them, the supply of missile troops with missiles and with missile fuel were planned separately. The plan for supplying troops with missiles was worked out by the directorate of artillery armament of the front, while the staff of the front rear services, jointly with the directorate of fuel supply, worked out the plan of missile fuel supply. Such a planning procedure required the staffs and services to conduct very complex work in the coordination of many questions: the stockpiling and echelonment of stocks, the determination of the time and periods of missile and missile fuel delivery, the use of various types of transport, etc. All this reduced the operational efficiency of the rear services work to a considerable degree and not infrequently led to errors in supplying the missile troops.

We believe that the planning of missile troop supply must be carried out in the following manner. In the front (army), it is necessary to work out a general plan of supplying missile troops with missiles, special charges, missile fuel, and other types of materiel supplies. A limited number of officers from the rear services staff, the artillery armament service, the fuel supply and other interested services, should be involved in the working out of this plan, conducting all the work in close coordination with the operational directorate (section) of the front (army) staff.

In our opinion, the following basic questions must be reflected in the plan which is being worked out graphically on a chart with a supplement of the necessary computations:

--the expenditure of missiles, special charges, missile fuel, and other materiel supplies for the missions of the operation;

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

--the volume and echelonment of missiles, special charges, and missile fuel stocks;

--the capabilities of rear services units and installations of the front for the assembly and servicing of missiles and special charges;

--the organization of transport of missiles, special charges, and missile fuel with the employment of the various types of transport;

--the disposition, and method and periods of movement in the course of an operation, of front missile-technical bases and dumps of missile fuel, and also other rear services units and installations intended for the support of missile troops;

--the organization of control, protection, and defense of missile-technical bases, depots, and other rear area installations.

The plan must be signed by the deputy troop commander for rear services and the commander of the artillery, and after coordination with the staff it must be approved by the troop commander of the front (army). In the development of the general plan of missile troop support, it is expedient for the directorates of artillery armament and fuel supply to work out more detailed plans for supplying troops with missiles, special charges, and missile fuel.

For example, in the plan being worked out by the directorate of front fuel supply, data can be reflected concerning the weight of missile fuel supplies of the front (army), the expenditure of missile fuel by tasks and days of the operation, the norms and echelonment of fuel supplies in units, the army, and in front dumps, a detailed estimate of the delivery of missile fuel to front missile-technical bases and to front depots, and also other questions.

The proposed method of planning, in our opinion, will permit comprehensive consideration of missile troop needs and the most

[redacted]

1.3(a)(4)

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

purposeful organization of their materiel, technical, and medical support.

The operational efficiency of front (army) rear services work in the comprehensive support of missile troops will be determined in many respects by the reliability and precision of control and the organization of rear area communications. Experience of exercises shows that for the direction of missile troop support, it is advisable to have a special radio net in the communications system of the rear area, permitting the organs of the front (army) rear services to control directly and uninterruptedly the front missile-technical bases and rear services subunits of missile units and large units. Furthermore, a general rearservices communications system with top-priority allotment of equipment and channels of communications can be employed for communications with rear services units and installations intended for the support of missile troops.

* * *

The considerations stated concerning the principles and procedure of missile troop support originate from existing views of their combat use and organization with regard to the technical level of missile weapons currently attained. However, the development of technical thought in the realm of missile technology is proceeding so rapidly that we must constantly consider its further improvement.

The simplification of missile design and the increase in accuracy of their use, not only with special but also with conventional charges, can be expected soon. All this will lead to a further extensive saturation of large units and operational formations with missile weapons, to a change in the organizational structure of the missile troops, and also to an increase in the expenditure of missiles in battle and in an operation. The feasibility of performing the assembly of missiles in the deep rear and transporting them in ready condition over a great distance will arise. Then the support

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

of missile troops included in the front and army composition can be organized along the existing system of supply of combined-arms units and large units with standard types of materiel supplies, taking into consideration only the specific peculiarities of storing, transporting, and servicing missiles.

In conclusion, it should be noted that the manner and methods of missile troop support examined in the article require further detailed study and testing in exercises.

SOURCE : A reliable source (B).

Following is a verbatim translation of an article titled "The Nature of Modern Armed Combat", by General of the Army A. Gorbatov.

This article appeared in the 1960 Third Issue of a special version of Voyennaya Mysl (Military Thought) which is classified TOP SECRET by the Soviets and is issued irregularly. It is distributed within the Ministry of Defense down to the level of Army Commander. The 1960 Third issue was sent for typesetting on 17 October 1960.

The Nature of Modern Armed Combat

by

General of the Army A. Gorbatov

It is absolutely clear that without the seizure of enemy territory, notwithstanding the power and the maximum effective range of modern combat weapons, it is impossible to achieve victory in war. Reaching the Atlantic coast of Europe, the area beyond the Pyrenees, or the penetration of "the toe of the Italian boot" will not yet signify the end of a world war, because the basic military-economic potential of the aggressive blocs is located across the ocean.

In recent times it has been possible to hear opinions that in the course of several hours or days it is possible to perform not only the basic strategic tasks, but even the tasks of the entire war, and also that, "the example of the capitalistic countries, annihilated in the first days of the war, will hardly evoke enthusiasm in the remaining countries for its prolongation."[1]

One cannot reason in this manner, one cannot flatter oneself with the hope of an easy victory, and it is harmful to sit back complacently and rely upon a short war. The authors of such statements probably forgot that the enemy is strong, that he also has nuclear/missile weapons, aviation, motorized troops, and a navy, and that not we but the enemy, will attack first. If the thoughts of these authors are projected, then one can convince oneself that the enemy, attacking first and having the same weapons as we have,

---

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

will also advance in lightening manner and achieve victory in the very shortest periods. No, this cannot be, and not for the reason that the Soviet people possess such clearly pronounced advantages as great endurance, patriotism, singlemindedness with their Communist Party and Government, but because war between the two world systems cannot be of short duration!

Speaking of the role of nuclear/missile weapons, in our opinion, it is basically wrong to think, much less to write, that "nuclear/missile weapons have replaced artillery and aviation". Nuclear/missile weapons increase many times the destructive power of aerial bombs and artillery shells, but cannot replace them. Replacement has not occurred and will not occur, not because in the enemy's infantry divisions the quantity of artillery and machine gun tubes is constantly increasing, but because the fate of operations and war will be decided by the sum total of all forces and weapons.

The last war proved the worthlessness of the theory concerning the exclusive role of aviation or tanks capable, seemingly, of independently deciding the outcome of the war. Now a new "theory" has appeared--to decide all the aims of war "with sufficient quantities of nuclear weapons", ignoring and belittling the role of other types of armed forces. And what should one understand by, "a sufficient quantity of nuclear weapons"? Of this no one says anything, and cannot say anything because this depends entirely upon how many nuclear weapons the enemy will have. Much also depends on the extent to which the weapons are skilfully used and on the quality of intelligence. Depending on this, it is sometimes impossible even with the availability of a large quantity of nuclear weapons to achieve such results as can be attained with an insignificant quantity of these same weapons.

Let us turn to what is, in our opinion, a very important question concerning the beginning of war, which should not be confused with the initial period of a war. Even though the enemy's combat operations started by a surprise attack can strongly influence the course of operations of the initial period, the beginning of war will be counted nevertheless in terms of several days, and the initial

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

period--in terms of months. The initial period of a war, by our accepted definition, extends to the moment of fulfillment of the first strategic missions. There is no objection to this. But when the first strategic missions are planned only in one variant, without considering the situation, i. e., the accomplishment of missions is envisaged only on enemy territory, then we cannot agree with this. In order that our military art might not be one-sided, the fact should also be considered that the first strategic missions can also be fulfilled on our territory, in the case of repulsing an enemy invasion, especially in the event of his surprise attack.

The decision for a surprise attack will not be made by parliaments or cabinets of ministers of imperialist states, but by 3 to 4 heads of states, or possibly even by one of them, from the other side of the ocean. Their commanders-in-chief may not even know about this beforehand. The regular, large NATO maneuvers may serve as cover for a surprise attack. Prior to the moment of attack, obviously, not even partial mobilization will take place, the normal operation of railroads and air and sea transport will be maintained, and city life will not change.

The possibility of a provocation on the part of the Pentagon is not excluded, when nuclear bombs may be dropped on the cities of NATO allies of the USA and at the same time the whole world will be informed by radio that other "Red" aircraft are being successfully repelled at the approaches to the USA, thanks to the perfection of the American antiaircraft defense (PVO) system.

It need not be doubted that the attack on the countries of the Socialist Camp will be accomplished, not during the summertime, as is usual, but in the fall or winter, during the period of extended darkness. It may happen that this will coincide with the discharge of older servicemen from the Soviet Army, when the drafted youngsters have not yet completed training.

It is necessary to assume that all ground, air and sea large units of NATO, including various missile bases, aircraft carriers, and missile-carrying vessels, already have sealed orders, in which

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

are indicated the initial and follow-up missions, the departure positions of ground large units, the targets for carrying out missile strikes with nuclear and conventional charges, with aviation, etc. Sealed orders will be opened upon a specific signal. It also cannot be excluded that during the course of maneuvers, prior to the signal for opening the sealed orders, ground troops, aviation large units, vessels, and missile units will be moved to those very areas which are indicated in the sealed orders.

Unfortunately, among many of our responsible military chiefs themselves the thought still lingers that we will learn in advance of the strike being prepared and that we will have time to adopt various measures. In our opinion, there is nothing more dangerous than such lack of concern. It should be clear that we must always be prepared for the worst. But if we have prior knowledge of an attack being prepared, then, naturally, we shall be able to do much beforehand. To foresee all the measures connected with minimizing losses during a surprise enemy attack is not easy and to carry them out is more difficult, but thought and work must be given to this now.

It is necessary to suppose, it appears to us, that the violation of our borders along the entire perimeter will take place simultaneously with all forces and weapons available to the enemy, and approximately in the following manner. The air forces, numbering up to 20 thousand bombers, fighters, and reconnaissance aircraft, will fly at low and high altitudes individually, in small groups, and in subunits of several tens of aircraft. Each aircraft, group, and subunit will have its own special missions: some will carry bombs with nuclear charges, others with conventional charges, and still others with chemical and bacteriological agents. If the attack is carried out during the evening of the longest night, then the aircraft will return before sunrise and will be able to ready themselves for a daytime sortie. All fighters will also carry bombs, in order to destroy as many of our troop garrisons, airfields, and border radar stations as possible. These fighters after several hours will not only return to their bases, but will also have time to ready themselves for repelling our bombers and to afford cover to targets. All reconnaissance aircraft will cross the border simultaneously with other aircraft to conduct reconnaissance

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

of missile launch sites, control and adjustment of fire of their own missiles, the detection of new targets, as well as the intersection of our radar stations in the zone of interior during their operation.

The enemy navy will be able to inflict nuclear/missile strikes not only on sea, but also on land targets located along the shore and in the zone of interior of the mainland.

Ground troops, located in the interests of concealment at a distance of 100 to 150 km from our border, might be on the border at dawn,provided the attack is carried out on the eve of a long night. The enemy divisions will proceed along separate axes, having the common plan after the surprise nuclear strike of breaking into our territory and disrupting mobilization. The rate of their advance will be guaranteed by organic and supporting nuclear/missile weapons, aviation, and landings (drops) of airborne forces on the main axes.

Considering subversive activities as third in order of significance in achieving the strategic goals of the war, after nuclear weapons and the combat operations of the troops, especially in the initial period of a war, during the first nights after the attack, for diversionary purposes, our probable enemies will drop small groups which have been specially trained, from among displaced persons. Special aircraft will disperse tens of millions of leaflets, primarily in the countries of the Peoples' Democracies, with an appeal to the population to aid the NATO troops, to leave work in enterprises, and to depart from the cities to escape nuclear attack.

It must be noted that a surprise attack provides the enemy certain advantages which will be more appreciable if we prepare ourselves poorly for repelling the strikes. Therefore, it is essential to envisage, and when possible, to carry out now such measures as, for example:

---expediently beforehand to find alternate sites for border radar stations in order that they may be transferred there during the time of an alert, leaving mock-ups at the old sites;

---at the time of NATO troop maneuvers which are by their nature suspicious, to move troop units from their places of permanent billeting

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

on exercises to the field and to take ammunition with them;

---while conducting regular reduction of the armed forces, to strive not to leave in one city entire large units, to avoid by every means possible the location of large headquarters in cities which might be primary subjects of nuclear attack;

---under conditions of the broad development of the construction of industrial and housing installations in the Soviet Union, it is necessary to try to obtain agreements with local authorities, and sometimes to turn for help also to the central agencies to build military camps outside large cities; to turn over existing military structures to appropriate agencies as factories, hospitals and schools, and officers' clubs as apartments for the local population;

---to have copies of mobilization documents of the oblast military commissariat in one of the rayon centers 30 to 50 km from the oblast center so that it might be possible to continue work if a strike is made against the latter;

---in case of a surprise attack against a border troop garrison as a result of which it will not be in a state to carry out previously assigned missions, to plan an alternate operational variant with a limited mission;

---to provide methods for the timely receipt and rapid transmission of information concerning an impending attack and to determine security measures connected with this;

---to organize precise coordination of radiotechnical units, permitting the detection of a massive buildup of enemy aircraft and their flight in the direction of our borders, the instantaneous notification of the PVO system, troop garrisons, airfields, naval bases, and other installations; good organization of notification will secure us 20 to 30 minutes of time; though this is not much time, with increased combat readiness it will be sufficient to bring all forces and weapons into action;

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

---it is essential to move our bomber aviation from the border zone to the zone of interior of the country, since it will be needed only for a counterstrike, and to turn its airfields over to fighter aviation, in order that the latter might strengthen the PVO of the Country in distant approaches to the maximum extent; the location of not more than a regiment at one airfield will hasten the takeoff of fighters and will lessen the losses in case of a strike on the airfield; subunits of reconnaissance aviation can be based with fighter aviation;

---to assign missions in advance to our reconnaissance aviation for reconnoitering definite zones in order that it might act upon their execution a minimum amount of time after the alert.

---to stop providing the enemy with important intelligence information. In the central papers it is frequently possible to see diagrams showing new industrial installations which have appeared during the last five-year plans; for instance, a map of Kazakhstan with an exact indication of the locations of new industrial centers and their production capacities; a great deal of varied information characterizing our econpmy may be obtained from republic and oblast papers; and some responsible individuals--deputies of the Supreme Soviet of the USSR, speaking at sessions in the presence of foreign correspondent-spies provide precise information concerning the types and volume of production output and the location of installations;

---to train groups at enterprises in cites who could save the wounded and materiel wealth in case of necessity; to provide for the formation of analogous groups in areas adjacent to the cities to provide assistance to the population of the city;

---to organize the delivery of fuel by means of pipelines to the western border.

The first priority mission in case of an attack must be considered to be the preservation of the armed forces and installations of the country because without this it will not be possible to carry out a powerful counterstrike. For the execution of this mission, weapons, forces,

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

and time must not be spared. This is why we must not allow carelessness and must concentrate all our attention on raising the combat readiness of the troops and their vigilance.

We reject the opinion of comrades who state that "upon the initial operations will depend the outcome of the war". Because he attacks first the enemy may have success in the initial and follow-up operations, but this does not mean that the outcome of the war will be predetermined.

One cannot agree either with the statement that, "after our counterstrike the enemy will go immediately over to the defensive". The enemy does not attack to give up his goals easily and go over to the defensive.

The opinion that "the initial surprise strikes do not frighten us because we possess a large territory, and the administrative and industrial centers are dispersed over it" is no good at all. The enemy will deliver a strike not over the entire territory, but on targets of which he has prior knowledge. If we are to speak of territorial dimensions in general, then the enemy, if one considers the territory of her allies in various pacts, as well as the expanse of Africa and Latin America, covers a territory no smaller than that of the Warsaw Pact countries.

Is it proper to reassure ourselves with the thought that after our counterstrike, the enemy, "will have undestroyed only a border strip with a depth of several tens of kilometers", that "the taking of this strip will then become the primary mission" of the ground troops, moving at a rate of 80 to 100 km during a 24-hour period, and in the depth we shall meet neither operational nor strategic reserves? No, this is not correct, and we should not exclude the possibility of waging stubborn and difficult battles, considering as well that our troops may also suffer losses as a result of the initial enemy surprise strike. It is inconceivable that, once having reached enemy territory, we shall not encounter his reserves. But it is also possible that separate large units of ours, notwithstanding enemy resistance and obstacles encountered, may penetrate deeply into the enemy dispositions.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The authors of some articles consider that the initial operations will start with a small number of combat-ready divisions and that reinforcements will enter later, or not at all. Others even claim that there will be no need for reinforcement because the enemy will have few forces left and it will only be necessary to crush them and occupy his territory. Is it possible to have such absolute disregard for the 60 combat-ready and well-equipped large units of NATO? It is not an exaggeration if we say that this opinion is absurd. We cannot assume complete combat ineffectiveness on the part of the enemy or, similarly, consider our large units approaching from the depth as not providing help. Notwithstanding the large number of obstacles which will be encountered along the path of their progress, some large units will advance at a rate of 100 to 150 km, and others at a rate of 200 to 250 km, in a 24-hour period. As a result, even those large units which were located 1000 to 1500 km from the border can be included in the composition of a front on the tenth day, i. e., after the front, having repelled the attack, advances onto the territory of the enemy.

The fact must also be considered that even after our counter-strike up to 30 NATO infantry and tank divisions will be on our borders, some of which will invade our territory, and the remaining 20 to 30 large units of those available at the present time will follow after the first echelon in one to three 24-hour periods. In this case, the essence of the first front operations (for a period of 2 to 5 days) will consist of fierce meeting engagements, as a result of which on one axis we shall overthrow the enemy and pursue him, on another will conduct combat with varying success, and on a third the enemy may penetrate into the depth of our country. These operations may be conducted with the intensive support of missiles and aviation utilizing nuclear and chemical weapons, with great effectiveness against rear area installations, communications lines, railroad junctions, and bridges, and with reinforced reconnaissance on both sides. Only after the engagements of these days and after heavy losses suffered by both sides, is the tendency noted to go on the offensive on one axis and on the defensive on another.

The offensive will be characterized by the rapid replacement of one form of combat by another. Swift and skilful operations with the use of all types of troops and good reconnaissance will frequently

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

compensate for inadequate forces and weapons.

In connection with the appearance of new combat weapons, the motorization of troops, and more versatile intelligence, special significance is acquired by the rapid evaluation of a situation and the making of a decision. He who hesitates in search for a better decision or who waits for direction from above, will frequently be beaten.

Some authors think that General Headquarters (Stavka) will not assign missions to the front, prescribe forces, weapons, the direction of the main strike, and the beginning of the offensive. They oppose the selection of the direction of the major strike as an antiquated, harmful concept. This opinion appears to us to be incorrect.

The General Headquarters' directives and orders to lower-ranking commanding officers will also have their place in the future. They will not undergo major changes in their content, but will only reflect the utilization of new combat weapons. The selection of the direction of the main strike and the specification of the forces and weapons for it will remain. Along this axis the basic strikes with nuclear weapons will be inflicted, a large portion of the tank large units will be concentrated, operational airborne forces will be dropped (landed), and the services of aviation and other means will be enlisted. It is clear to everyone that we are not referring to some sort of condensation of groupings.

The recommendation to refuse to surround enemy groupings and to form a ring around them, but to annihilate the cut-off groupings only with reserves and nuclear weapons, is unacceptable, in our opinion. Up to now, the best method to annihilate and capture the enemy has been to surround him, and for this reason one cannot dismiss it. In the future, despite the thinned-out combat formations and offensives along separate axes, one must always strive to come out on the enemy's route of retreat, to cut him off, and to surround him with a portion of one's forces, while continuing to advance with the basic forces. There will also be instances when it will be necessary for a portion of the

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

forces to advance and for the basic forces to surround the enemy. It is not expedient to create a compact or complete ring, but rather to surround the enemy by intersecting all routes to limit his movement; otherwise he will withdraw to a new line and will be able to provide resistance even before the approach of his reserves.

Some authors demand that we give up the training of troops in breaking through an established defense of the enemy, because it may be annihilated by nuclear weapons or bypassed. However, if we do not train the troops in this, then with a shortage of nuclear weapons and the impossibility of bypassing the defense of enemy troops from the flank, we will find ourselves in a difficult situation. For this reason, in our opinion, we must train the troops in everything which may be encountered in war. In addition to this, we do not always know how many and which types of nuclear weapons are available in our depots, much less those which the enemy has. It may be supposed that in the first days of a war nuclear weapons will be used abundantly, and in the succeeding period in a more limited manner, because the plants producing these weapons will begin to be destroyed more rapidly than they can be restored. With the limited use of nuclear weapons, the role of aviation, tanks, and artillery will be raised, and we will more frequently encounter positional defense of the enemy.

The mission of our defense in the future will still remain the disruption of the enemy offensive. Its execution will be possible provided there is a combination of stubborn defense of the main points and installations with counterattacks, counterstrikes, and the utilization of nuclear and other weapons of mass destruction. The defense system will depend upon zones, positions, and continuous trenches. In order to avoid a stereotyped formation, and with the aim of optimum utilization of the terrain, the number of zones, positions, and the trenches within them will vary. Their depth and design will not be the same. In this light we consider especially harmful the opinion expressed by General A. Gastilovich against the creation of zones of defense and the continuous trenches within them, an opinion based on the theory that the troops defending them will be annihilated or bypassed. It is quite clear that if those troops situated in the defense can be annihilated, then those advancing without benefit of cover are all the more

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

subject to the same treatment. General A. Gastilovich expresses an incomprehensible pity for amphibious landing force of the enemy on the sea and recommends that they be destroyed by missiles alone! And why not hit it with aviation and naval forces? He does not recommend the erection of obstacles in places suitable for a debarkation of inflicting strikes on the enemy at his most critical moment in the debarkation on shore, but proposes destroying the enemy only on the shore and only with tanks. This is completely incomprehensible.

The Influence of Nuclear Weapons on the Principles of the Offensive Operations of a Front

by

General of the Army V. Kurasov

The rapid development of the socialist economy and of Soviet science and technology testify more eloquently than any words that our nation is successfully creating the material-technical foundation for Communism and at the same time is increasing its defensive capability.

The Soviet Armed Forces, while undergoing reduction in numbers, are being equipped more and more with nuclear weapons and other means of modern military technology. A new type of armed force has been created--missile troops of strategic designation. The equipping of all types of armed forces with nuclear weapons in quantity that will ensure their mass use in operations immeasurably increases their combat capabilities. All this introduces radical changes in our views on the nature of modern warfare and the methods of waging it.

History offers many examples of how the development of armament and technology has given rise to great changes in views on warfare and in military art, but the revolution in the field which is occurring at the present time, mainly on account of the development of nuclear weapons and the possibility of their mass use, cannot be compared with the changes of the past. The radical modern changes in views on warfare and in military art have the nature of a headlong gallop, a break with the gradual development of military art, which signifies the elimination of a number of old tenets and their replacement by new ones.

By their own combat capabilities, nuclear, and especially nuclear/missile, weapons under conditions of their mass use are the principle

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

means of armed combat, and have a decisive influence on the course of operation of all types of armed forces. Moreover, these weapons have altered the combat capabilities of even identical types of armed forces. One cannot now, for example, imagine the nature of offensive operations of a front and the means of conducting them without an analysis of the possible influence on them of strikes of nuclear weapons of strategic designation and various types of armed forces participating in these operations. Thus, during and as a result of strikes by nuclear weapons of strategic designation, as we can well imagine, nuclear superiority over the enemy can be won, his economic power can be undermined, and the destruction of the strategic groupings of his ground troops, air forces, and navy can be attained.

It remains to be said that such nuclear strikes will as a rule be inflicted on enemy objectives located in the strategic depth. Therefore, despite the views stated in the article by Colonel-General A. I. Gastilovich,[1] the destruction of enemy objectives in his tactical and operational zones is the goal of the offensive troops of a front and above all of their nuclear weapons, and not the target for nuclear strikes of strategic designation. Of course, one cannot completely exclude cases where such strikes of strategic designation may be delivered against enemy objectives in his operational depth. However, these cases will not be typical, owing to the fact that such use of strategic nuclear weapons contradicts their designation and does not completely exploit all of their combat capabilities.

Success of these powerful strategic nuclear strikes, especially if they precede the beginning of an offensive operation of a front, will undoubtedly ensure favorable conditions for the conduct of the operation with a comparatively small expenditure of nuclear weapons of the front. Under other conditions, when nuclear weapons of strategic designation are not employed in the area of the offensive of a front, the successful attainment of the goal of the offensive will require the use of a greater number of the nuclear weapons of the front.

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

Not too long ago, during our command-staff exercises, the front, having a limited amount of nuclear ammunition, was able to deliver nuclear strikes only against the most important, individual targets and objectives of the enemy, while a substantial portion of other targets and objectives continued to be destroyed by conventional weapons. And if it is recalled that practically the only carrier of nuclear weapons at that time was aircraft, which often did not reach the target, then one can even more fully understand the insufficient effectiveness of nuclear strikes of that period. In connection with the limited use of nuclear weapons in offensive operations of a front, the possibility of simultaneous destruction of enemy groupings and objectives in the entire depth of their operational formation was precluded during our exercises at that time. Therefore, the troop offensive, as in the past, was carried out through the successive overcoming of enemy resistance, during which the enemy had the opportunity to maneuver his forces and weapons from the rear and the flanks for the creation of strike groupings.

Thus, nuclear weapons under conditions of limited use still had not introduced decisive changes in the structure and conduct of offensive operations of the front.

Only now, with the mass employment of these weapons in operations with the use of various delivery vehicles, mainly missiles, is it possible to deliver surprise nuclear strikes against a significant number of enemy objectives and achieve their rapid and complete destruction. Without exaggerating, it can be assumed that with the successful mass use of nuclear weapons in an offensive operation of the front, not less than 60 percent of the entire opposing enemy grouping will be destroyed with these weapons. This is why nuclear, and especially nuclear/missile, weapons have now become decisive in the destruction of the enemy and above all in the attainment of nuclear superiority over him. The attainment of such superiority will significantly quicken the destruction of enemy groupings, while in the absence of this superiority the enemy will always have an opportunity to disrupt our offensive through the mass use of his nuclear weapons.

[redacted]

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Only now in connection with the development of nuclear, and principally nuclear/missile, weapons, and also in connection with the possibility of their mass use, are radical changes in the structure and conduct of offensive and other operations taking place.

Let us examine several more specific instances of the influence of nuclear weapons on some of the principles of offensive operations of the front in the initial period of a war.

The goals of an offensive operation of a front, as is generally known, determine its concept and scope. Such goals, as in the past, are: the destruction of the basic enemy groupings, the swift development of the offensive, the seizure of his territory and specific operational-strategic objectives. However, the essence and nature of these goals have changed considerably. While, in the past the basis of the enemy's grouping of troops consisted of his infantry and tank large units, now nuclear weapons, as the principle and decisive means of combat, have become the basis.

Studying the development of nuclear weapons of operational-tactical designation in the armies of the probable enemy and above all in the US Army, we come across a great number of types of nuclear weapons, of TNT equivalents and of delivery aircraft. Quite recently, up to 10 types of aerial atomic bombs with 19 various TNT equivalents (from 2 to 300 kilotons) could have been noted in the US Army. Seventeen different types of delivery aircraft supported the use of these bombs.

At the present time the arsenal of nuclear/missile weapons of operational-tactical designation in the US Army consists of only five types of guided missiles and free rockets: "Honest John", "Little John", "Lacrosse", "Corporal", and "Redstone" with nine different TNT equivalents (from 1 to 3800 kilotons), and two types of cruise missiles: "Matador" and "Regulus" with five TNT equivalents (from 1 to 100 kilotons).

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Furthermore, it should be noted that the probable enemy has at his disposal artillery pieces with calibers of 203 and 208 /sic - 280/ mm with nuclear shells (from 1 to 45 kilotons).

As is evident from the aforementioned data, the most modern and powerful nuclear/missile weapons in the armies of the probable enemy have not yet become his principle and decisive means of combat. It looks more as if the enemy's aviation still fulfills this role, in spite of its increased vulnerability to antiaircraft missiles. This should be kept in mind. However, this situation requires further study.

As regards the possible number of enemy infantry and tank large units in his troop grouping, able to resist the front, considerable changes have also taken place here. Comparatively recently, under conditions of limited use of nuclear weapons, it was considered that in a front offensive area with a width of 300-400 kilometers, and basing the average operational density of troops at 15 kilometers per division, the enemy could have up to 20-27 infantry and tank divisions. Because of the mass use of nuclear weapons, these divisions can now successfully advance and conduct combat operations in areas with a width of up to 30 kilometers, and such an enemy grouping will undoubtedly be smaller. For example, in a front offensive area with a width of 400 kilometers, it will have in all only 13 to 15 infantry and tank divisions. Such a quantitative reduction of groupings is a direct consequence of the unusually increased fire power and troop maneuverability, and also of the requirement for their maximum protection from destruction by nuclear weapons.

Together with this, the dispersal of enemy groupings in area has grown even more. Now it is impossible to imagine compact groupings with a continuous front of even one or two enemy divisions, to say nothing of several of his armies, since such groupings would immediately be subjected to nuclear strikes and destroyed.

Under modern conditions, not armies, but often individual enemy divisions, not creating a continuous front, will conduct an engagement in a particular area, while others of his divisions on the flanks and

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

in the rear of this area execute a maneuver with the aim of a swift penetration ahead. Hence, the enemy grouping will not only be smaller with regard to its force and composition, but also more widely dispersed in area.

Finally, mention should be made of the great influence which the mass use of enemy nuclear weapons has on the nature of his troop operations, accelerating them significantly. The offensive operations of the probable enemy during his training exercises acquire a deeper and more dynamic nature. The enemy has recourse less often to the solution of tasks by shifting to the defensive, and even the latter has begun to have a different, more aggressive, and maneuverable nature.

Thus, the modern enemy grouping has become not only smaller in relation to its force, and more widely dispersed in area, but also more aggressive and maneuverable with regard to the methods of the execution of operational tasks.

Regarding the operational-strategic enemy objectives which may be the goal of a front offensive operation, it should be emphasized that under conditions of mass use of nuclear weapons, their destruction, seizure, and retention will no longer create difficulties as in the past and will not require as large forces as were used for this during the past war.

A true conception of the probable enemy, a careful study of his strong and weak points, and also their skilful exploitation during the preparation and conduct of an offensive operation, will ensure his rapid and most complete destruction.

The forces and weapons needed for the conduct of a front offensive operation determine the success of the operation to a large extent. As is well known, the basis for the determination of such forces and weapons was always the demand for the creation of the appropriate superiority over the enemy. The stronger and more aggressive the enemy was, the more forces and weapons were

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

required for his destruction, and consequently, the more significant was their superiority over the enemy, and as long as superiority of forces was not attained, the front offensive operation often did not begin. This was true in the past and, incidentally, quite recently under conditions of limited use of nuclear weapons.

Now that the possibility of the mass use of nuclear weapons has become a reality, the relative strength as a result of powerful nuclear strikes of the offensive side can rapidly and sharply change in its favor even at the very beginning of the operation.

Since, as a result of such powerful nuclear strikes, the front can destroy not less than 60 percent of all enemy forces and weapons at the beginning of the operation, then the general superiority of his forces and weapons over the enemy can become significant, and on the axis of the main strike, even great. However, this can occur only if the offensive troops themselves have not already suffered enemy nuclear strikes. Therefore, under modern conditions, the necessary superiority of forces and weapons over the enemy will as a rule not be attained prior to the beginning of the offensive operation, as it was previously through the concentration and deployment of these forces on appropriate axes, but at the beginning and in the course of the offensive operation as a result of the infliction of powerful nuclear strikes on the enemy.

Thus, under conditions of the mass use of nuclear weapons, the front offensive operation can be successfully conducted even with equality in the relative strength of forces and weapons.

The influence of nuclear weapons affects not only the quantity of forces and weapons of the front and their relative strength, but also the combat composition of a front. The most important place in this combat makeup is now occupied by nuclear weapons, and principally by missile troops. An estimate of other forces and weapons included in the combat composition of the front depends on a correct and accurately grounded estimate of the necessary quantity of these weapons.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

For an estimate of the nuclear weapons needed for the entire offensive operation of a front, it should be taken into account that for a reliable destruction of all selected targets and objectives, it seems to us that we must allot from 4 to 6 nuclear weapons of appropriate TNT equivalents against every large unit and operational-strategic objective of the enemy, or 1 or 2 nuclear weapons of high yield (100-500 kilotons). Such an estimate will permit, even if only approximately, the determination both of the overall number of nuclear weapons needed for the operation and of their types and level of yield. In its turn the estimate of the nuclear weapons of a front depends on what tasks will be carried out in behalf of the front by nuclear weapons of strategic designation.

The strength and composition of the motorized rifle and tank troops of a front are determined in accordance with the combat potentialities of the nuclear weapons of the front, the operational density of the enemy grouping, and the tasks of these troops in the operation.

In view of this, the front grouping cannot be permitted to have a lower operational density of troops than the enemy. Let us suppose that the front grouping of troops has an operational density of troops, equal to 20 kilometers per division. Then a front offensive area having a width of 300 kilometers must have no fewer than 15 divisions in its composition. Furthermore, additional forces and weapons should be provided, to allow for possible losses of our troops in the course of the offensive operation and for the appearance in the area of the front offensive of fresh enemy troops or of enemy troops who have escaped destruction. In the case of limited use of nuclear weapons, the estimate of the forces and weapons of a front must include appropriate adjustments for an increase in the number of motorized rifle and tank large units.

The tasks of the motorized rifle and tank troops in a front offensive operation are also determined by these conditions. While, under conditions of the mass use of nuclear weapons, the basic task of these troops is the completion of enemy destruction upon whom nuclear strikes have been inflicted, in the case of the limited use of these

[redacted] 1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

weapons the motorized rifle and tank troops of the front will fulfill the basic task of destroying the enemy grouping.

The destruction and neutralization of the enemy in his tactical and operational zones may require reinforcement of the front with artillery, which at the beginning of the offensive and especially in the operational rear, will unquestionably render great benefit to the offensive troops in overcoming the centers of enemy resistance which have survived nuclear strikes.

Taking into consideration the increased role in an offensive operation of a front of airborne troops who are capable of seizing the most important areas in the enemy's operational rear more quickly than other troops, their forces in the effective strength for combat of the front should be especially accurately determined, starting with the tasks that can be assigned to them. Furthermore, one should keep in mind that in a modern offensive operation of a front, which is conducted against a considerably greater depth, airborne landings on a tactical and operational scale may have a place in the combat makeup of the front.

Large units and units of engineer troop reinforcement may enter into the combat composition of the front when the front's own (shtatnyy) engineer resources are not able to support a maneuver of troops or the rapid rate of their advance, especially during a crossing in force of water barriers or during operations in zones of radioactive contamination.

The strength and composition of the aviation of a front are also determined in accordance with the tasks which will be assigned to it. Such missions in a front offensive operation may be: the conduct of reconnaissance, the destruction of mobile and small-sized objectives in the tactical and operational zones, and the support of the attacking troops of the front during the course of the operation.

It is particularly important in the combat composition of the front to have units of antiaircraft-missile troops, fighter aviation

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

and antiaircraft artillery in sufficient number to provide reliable air cover for the launching areas of missile large units and units, for airfields with delivery aircraft for nuclear weapons, for command posts, for basic troop groupings, especially in the areas of their concentration, and for the most important installations in the rear area of the front.

The selection of the axis of the main strike is the most important fundamental offensive operation, which in essence determines the concept and methods of conducting the operation. However, some authors of articles (Comrades Baskakov and Zavyalov), in their review of the principles of our military art, have expressed the view that under modern conditions the established opinions about the axis of the main strike are obsolete and may lead to the creation of concentrated strike groupings of troops, which would offer a highly profitable target for enemy nuclear strikes, and thus do injury to our military art. In connection with this, they propose either to abolish this most important principle of military art or to replace it with the principle of concentrating the basic efforts on the destruction of the nuclear weapons and the main troop grouping of the enemy or with the definition of the principle tasks of the operation, to the fulfillment of which the basic efforts of the weapons of nuclear attack and of the troops must be directed.[1] But are not such conclusions and proposals too hasty, and will they not inflict damage on our military art?

It has long been known that one cannot be strong everywhere in an offensive. Any such tendency has always led to the dispersal of forces and weapons, to strikes against the enemy with widespread fingers.

If this was fallacious before, then under present conditions of the mass use of nuclear weapons, such strikes are even more inadmissable, since they may lead not only to the dispersal of the

---

[1] Special Collection of Articles of the Journal "Military Thought", First Issue, 1960.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

troops but above all to the dispersal of nuclear weapons in various directions often of secondary importance. Of the several axes along which the troops of a front are advancing, one always will be decisive, i. e., the axis of the main strike, which usually involves the entire depth of the front offensive operation. Therefore, not only are strategic and operational-tactical factors to be considered, but also the possible influence of political, economic, and physical-geographical conditions on the course of the offensive operation. The axis of the main strike determines the concept of the offensive operation, the tasks of the front troops, and above all of nuclear weapons, and also the methods of fulfilling these tasks.

As for the proposed principle of concentrating the basic efforts on the destruction of the nuclear weapons and the main grouping of the enemy, these are nothing less than the most important tasks of the offensive troops, but they can be accomplished only when the areas of the location of the nuclear weapons and of the troop groupings of the enemy have been precisely determined. However, these tasks still cannot determine the concept of the front offensive operation and the methods of conducting it, since far from all the areas of location of the nuclear weapons and groupings of the enemy will be known to us prior to the beginning of the operation.

The same thing can also be stated regarding the main tasks of the operation, which have been proposed to replace the concept of the axis of the main strike since these tasks can likewise be assigned to the troops only after the establishment of the coordinates of the appropriate enemy targets and objectives. Thus, neither the principle of concentrating the basic efforts on the destruction of the nuclear weapons and the main grouping of the enemy, nor the main tasks of the operation, can abolish or replace the axis of the main strike.

One can likewise hardly agree with the view that the selection of the axis of the main strike leads to the creation of concentrated assault groupings of troops, which would offer a highly advantageous target for mass nuclear strikes. Is it not a fact that the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

axis of the main strike is not a line but a zone of terrain within the borders of which the troops advance? Why then cannot this offensive zone, with its width, ensure the necessary dispersal of troop groupings and the most effective use of their firing, striking, and maneuvering capabilities?

Such a dispersal of troops is now necessary as one of the most important conditions for ensuring the success of the offensive, and not only on the axis of the main strike but also on other axes. At the present time concentrated strike groupings of offensive troops will not be created on these axes. Very likely, on the axis of the main strike, as distinguished from other axes, a more powerful troop grouping will attack, but in a wide zone, thus ensuring the necessary dispersal and maneuver, while on the other axes of the advance the troops will be of less strength and not in such wide zones.

Prior to the mass use of nuclear weapons, the main strike was as a rule launched on the axis most likely to ensure the successful breakthrough of the enemy defense and the destruction of his basic grouping. Therefore the axis of the main strike almost always ran through weak sectors of the enemy's defense and took the attacking troops to the flank and rear of his strong grouping. It should be recalled that this was conditioned by the complexity of the destruction and neutralization of the enemy's defense system in its strong sectors and by the difficulty of penetrating this defense.

But now, under conditions where the mass use of nuclear weapons favors the rapid and most nearly complete destruction of an enemy of any strength, it is advisable to launch the main strike on the axis which will ensure the rapid advance of the troops and the seizure of the operational-strategic objectives of the enemy.

In accordance with the goal of the front offensive operation, in addition to the axis of the main strike, the axes of other strikes are also determined. It should be emphasized that at the present time the destruction of the enemy and the success of the troop advance on the axis of the main strike depend on the success of these other strikes to a greater degree than was true in the past. As soon as there occurs any confusion or even worse, any failure, in the advance of the troops

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

on the other axes, then the flanks of the troops attacking on the axis of the main strike are immediately exposed, the possibility of their isolation is increased, and favorable conditions are created for the enemy to destroy this grouping of the attacking troops.

Therefore the troops attacking on the other axes must have a sufficiently high penetrating ability and capabilities for maneuver, thus ensuring their swift advance. In other words, these troops must have at their disposal nuclear weapons and the appropriate reserves to the extent necessary.

The determination of the immediate and subsequent tasks of the front was always the most important part of the concept of the offensive operation and of the commander's decision. The distribution of front troop efforts for the fulfillment of successively resolved tasks takes place as a result of the fact that with one, even with the most powerful strike, it has been impossible to destroy the entire enemy grouping and to attain the final goal of the front offensive operation. But perhaps now, under conditions of the mass use of nuclear weapons and the increased combat capabilities of the armed forces, the final goal of the front offensive operation can be attained with the delivery of one powerful strike against the enemy grouping. However, an analysis of the combat capabilities of the enemy and of our modern armed forces does not allow us to give a positive reply to this question.

Even now not one, but several strikes against the enemy grouping, and also considerable effort and great stress on the part of the attacking troops, are required for the attainment of the final goal of the front offensive operation. In other words, even under modern conditions, the goal of the front offensive operation can be attained only as a result of the fulfillment of the immediate and subsequent tasks of the front. But now these tasks, principally under the influence of nuclear weapons, have increased in depth and have been abbreviated in the time needed for their fulfillment. Furthermore, with the availability of long-range missiles and of delivery aircraft for nuclear weapons, the fulfillment of a subsequent

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

front task can be begun at the same time as the destruction of the enemy and his tactical and closest operational depth, i. e., during the time that the front troops are fulfilling their immediate task.

Proceeding from the above, the immediate task of the front in a modern offensive operation must be understood to be the rapid and decisive destruction of the enemy grouping, and above all of his nuclear weapons, the swift advance of the troops, and the seizure of important objectives or areas to a depth of 300 to 400 kilometers, i. e., to the depth of approximately the entire front offensive operation in the last war. Taking account of the increased rate of advance of troops, the modern front can fulfill this task during 3 to 4 calendar days.

The subsequent task of the front will be to complete the destruction of the strategic enemy reserves by means of a swift advance of the troops and to capture the objectives and areas whose seizure will accomplish the final goal of the front offensive operation.

As is evident, the greatest importance is attached to the fulfillment of the immediate task of the front, in the course of which the destruction of the enemy's basic forces takes place and in essence the fate of the front offensive operation is decided. Therefore, the largest portion of all the forces of the front, and above all nuclear weapons, must be employed for the fulfillment of precisely this task.

However, under the conditions of the mass use of nuclear weapons by the enemy, and in connection with the increased role of his strategic reserves, the importance of the subsequent mission of the front has been increased, for the fulfillment of which the front will often have to be reinforced with the appropriate quantity of nuclear ammunition and with fresh large units of troops.

The methods of conducting an offensive operation of a front under the influence of the mass use of nuclear weapons has also undergone significant changes.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Soviet military art has always striven to find a method of conducting offensive operations which would lead to the quickest and most complete destruction of the enemy and to the attainment of the final goal of the operation. In the search for such methods, Soviet military-scientific thought, as is generally known, even in 1935 worked out the theory of combat in depth, which consisted in essence of simultaneous attack against the enemy to the entire depth of his combat formation. However, the firing, striking, and maneuvering capabilities of the troops of that time could not ensure the practical implementation of this theory. Nor was this problem resolved in World War II operations. Only now, in connection with the rapid growth of firing, striking, and maneuvering capabilities of the armed forces have conditions appeared for the practical solution of the problem of the simultaneous destruction of the enemy to the entire depth of his operational formation.

It is a fact that modern nuclear, and especially nuclear/missile, weapons can be successfully employed for the delivery of sudden, long-range, and crushing strikes against the enemy to the entire depth of his operational formation, and even against his strategic reserves.

The development of airborne forces and military-transport aviation, now as never before, ensures the dropping and combat operations of front troops not only in the immediate but also in the deep rear area of the enemy on the most important axes and in the decisive areas.

The increased mobility of ground troops, ensuring their advance at a speed of 100 kilometers and more, permits them to gain the enemy's operational-strategic rear quickly.

More than was true in the past, modern aviation ensures effective support and cover for troop combat operations to the entire depth of their offensive.

Thus, the increased firing, striking, and maneuvering capabilities of modern armed forces fully ensure the conduct of a front offensive operation in greater depth and completely resolve the problem of simultaneous destruction of the enemy grouping to the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

entire depth of its operational formation. Any other method of conducting a modern offensive operation which results in the consecutive, methodical advance of troops, is a step backward. It fails to exploit all the firing, striking, and maneuvering capabilities of modern troops, and permits the enemy to maneuver with ease in his operational rear and to create groupings for the launching of strikes against the attacking troops. The simultaneous destruction of the enemy can be accomplished through the annihilation and prolonged neutralization of his groupings and objectives on the axis of the main strike and on other axes, in the tactical and operational zones, at least to the depth of the immediate task of the front. The main role in the simultaneous destruction of the enemy grouping in the entire depth of its formation is carried out by the missile troops both of the front and of strategic designation.

Missile troops, in coordination with aviation, employing nuclear and chemical ammunition, destroy and neutralize enemy nuclear weapons at bases, depots, launching sites, and airfields, as well as his troop groupings and control centers. The missile troops, as a rule, deliver the most powerful nuclear strike at the beginning of the offensive. In the course of an offensive operation, the missile troops deliver nuclear strikes against newly discovered enemy targets and objectives opposing the attacking troops.

Chemical weapons are also employed, mainly against objectives which were not subjected to nuclear strikes, in order to ensure the most complete destruction of the enemy and to preclude the possibility of his counteraction and maneuver.

However, the transformation of nuclear strikes into the final destruction of the enemy, together with the seizure of his territory, requires the immediate carrying out of airborne landings and the swift advance of motorized rifle and tank troops in coordination with aviation.

Airborne forces quickly occupy the most important areas on the axis of the main and of other strikes of the attacking groupings in

[redacted]

1.3(a)(4)

1.3(a)(4)

[redacted]

[redacted] 1.3(a)(4)

coordination with the missile troops and front aviation; they complete the destruction of the enemy in these areas and prevent the approach of his fresh large units from the rear and from unattacked sectors, thus ensuring the swift advance of the troops into the operational depth of the enemy. With this goal, tactical airborne landings can be employed by armies at a depth of 100 to 200 kilometers from the enemy's line of defense, while operational airborne forces of a front can conduct combat operations at a depth of 200 to 400 kilometers and more. The basic conditions which ensure the success of airborne forces operations are the suddenness and rapidity of the landings, and also the aggressiveness and resoluteness of the operations during the execution of the combat tasks. However, for the reinforcement of operational airborne forces it will sometimes be necessary to increase their forces through the transfer by air of motorized rifle units and large units.

The motorized rifle and tank troops of a front, in coordination with missile troops, aviation, and airborne forces, by skilfull maneuvering and by not becoming engaged in protracted fighting with the enemy, can quickly overrun his tactical and operational zones, swiftly reach the area of the combat operations of the tactical and operational airborne forces, accomplish the immediate task of the front, and continuously develop the offensive to the accomplishment of the goal of the front operation. Artillery, and above all rocket artillery, destroys and neutralizes the enemy's nuclear installations, his weapons, and his personnel. In the course of the offensive, the artillery destroys and neutralizes newly discovered targets, objectives, and revived centers of enemy resistance.

The speed of the troop advance, especially on the axis of the main strike, must be not less than 100 kilometers per calendar day.

Aviation, in coordination with the missile, airborne, and ground troops of the front, destroys and neutralizes enemy nuclear weapons and troops, against whom missile strikes and artillery fire may not be sufficiently effective. It also supports and covers the attacking troops, destroying newly discovered (mainly mobile and small-sized) objectives and also enemy air targets.

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

It is obvious that such a method of conducting an offensive operation of a front in which all the combat capabilities of the attacking troops are used to the maximum, significantly hastens the destruction of the enemy and the attainment of the goal of the operation. However, it should be emphasized that this method of conducting an offensive can be successfully carried out only with the mass use of nuclear weapons, and even then only when the enemy troop groupings and objectives marked for destruction, are well reconnoitered and their coordinates precisely determined. Therefore, the method of the simultaneous destruction of the enemy to the entire depth of his operational formation can be used most often at the beginning of an offensive operation. Under other conditions, when the enemy groupings and objectives are insufficiently reconnoitered, and when the launching of a simultaneous strike against them to their entire depth does not appear possible, the front offensive will be conducted by means of the successive destruction of enemy groupings and objectives in accordance with their discovery and the precise determination of their coordinates. Such a method of conducting an offensive naturally cannot ensure the most complete utilization of all the firing, striking, and maneuvering capabilities of the attacking troops and it permits the enemy to maneuver in his depth with the aim of delaying and disrupting our offensive. Most commonly, the goal of the offensive front operation will be attained as a result of a combination of the methods of simultaneous and successive destruction of the enemy, with the first of these methods having the decisive role.

It should be emphasized that these methods of conducting an offensive front operation may be successfully employed for the implementation of any concept of the operation.

The grouping of troops in the offensive operations of the front consists not only of their operational makeup but also must provide for various procedures of the large units and units--marching, approach march, and combat. At present one cannot conceive of a front grouping solely in terms of the formation of the individual armies of which it is composed, without those formations of large units and units which, properly speaking, accomplish the operation.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

A troop grouping of a front and of armies, depending upon their tasks, can be varied, but must always and to the greatest extent possible, ensure the successful execution of these tasks. While the immediate task of the front is carried out through the launching of a simultaneous strike against the enemy in the entire depth of his operational formation, the front troops must strive to execute this task in one grouping. As a rule, in such a grouping the front troops will be formed into one echelon, following which the necessary reserves must be provided. It is impossible that in the course of the execution of the immediate task of the front, the situation will require changes in the grouping of the troops, but in this there should be no large-scale regroupings of troops.

The rapid and complete destruction of the enemy to the entire depth of the immediate task of a front must ensure to the grouping of troops a continuous and swift advance right up to the execution of the subsequent task.

When the immediate task of a front is to be carried out through the delivery of successive strikes against the enemy, and his complete destruction requires more prolonged and intensive combat, the most advisable grouping of a front may be formation into two echelons. In this case the second echelon of the front is usually committed to battle at the beginning of the execution of the subsequent task of the front.

The most important place in the modern grouping of a front is held by missile troops and delivery aircraft for nuclear weapons. Therefore the creation of a front grouping must begin with the determination of the siting areas for missile large units and units, and also for the airfields of delivery aircraft, and only after this can the assembly and departure areas of other front troops be laid out. Nothing must reveal the siting areas of missile troops or the airfields of nuclear delivery aircraft.

The departure areas of airborne troops must be occupied immediately before the beginning of airborne operations.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

As regards tank and motorized rifle large units, in the interest of achieving concealment of the offensive, they can pass through their departure areas without stopping, or else occupy them for the minimum time necessary for the deployment of artillery in firing positions, the inspection of equipment, and the refueling of tanks and vehicles.

The security of a front troop grouping from enemy nuclear strikes, as is generally known, is largely ensured by its dispersal. However, even in a dispersed state, troops must not be located for a prolonged time in the same areas. In this connection, now to a greater degree than previously, emergency areas, firing positions, and airfields must be provided, and also the arrangements for the concealed movement of the troops must be more carefully worked out. At the same time, the importance of counterintelligence in the areas of troop disposition, especially of missile troops, and on the routes of their movement has increased.

But skill consists not only of the creation of the most advantageous grouping of troops in a departure position, even though this is very important, but also of maintaining its advantages during the course of the entire offensive, taking into consideration that an enemy employing nuclear weapons can at any moment suddenly introduce large, unfavorable changes in the front troop grouping if appropriate measures are not taken by our side. The continuous maintenance of a favorable grouping of the attacking troops can be achieved through the timely delivery of sudden and crushing nuclear strikes against the enemy, thus exerting great influence on the course of the offensive, and also through the skilful maneuvering of the attacking troops. But such means of maintaining an advantageous situation and the superiority of our grouping will provide the necessary effect only if the command and staff of the front, in their planning and direction of the offensive operation, prudently determine the most favorable grouping of troops not only in the departure position but also during the crucial moments of the offensive, and also toward the end of the first and each of the subsequent days of operation.

Let us examine the problem of the influence of nuclear weapons on the scope and nature of the offensive operations of a front.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The width of a front offensive zone. It is known that under conditions of the mass use of nuclear weapons, the number of large units of ground troops in the composition of a front is reduced and their operational density considerably diminishes. In connection with this, the width of the front offensive zone now will ordinarily be determined by the established operational density of the troops, which in its turn will depend on the amount of nuclear ammunition alloted to the front. Under conditions of the mass use of nuclear weapons, this density will scarcely be higher than 20 kilometers per division. With such an operational density of the troops of a front, an offensive zone 300 km wide, e. g., may have 15 division, besides the necessary reserves. But if there are 20 divisions in the composition of a front, then for the same operational density of troops the width of the zone of its offensive will be 400 kilometers.

Thus, depending on the quantity of nuclear weapons alloted for the operation, the number of divisions in the composition of a front and the established operational density of troops, the width of a front offensive zone may now vary within the limits of 300 to 600 kilometers. A further increase in the width of a front offensive zone may cause considerable complications in the control of the troops. In determining the width of a front offensive zone, the relative strength of forces and weapons should not be forgotten and, even more, the enemy should not be permitted an overall superiority of them. Together with this, it is necessary to take into consideration that in the development of an offensive the front zone will widen, and toward the end of the operation its width may have grown approximately one and one-half times.

The depth of a front offensive operation is usually determined by the goal of the operation and by those installations and areas which are to be taken. Under the conditions of the mass use of nuclear weapons, including those of strategic designation, an offensive operation of a front in the initial period of a war can be carried out to a depth up to 800 kilometers and more, since at this depth the enemy's groupings and his most important installations can be destroyed as a result of nuclear strikes. Under conditions where a front does not have at its disposal the capability of delivering mass

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

nuclear strikes at such a distance, the depth of its offensive operations will, of course, be less.

The rates of advance of the troops can be varied and they depend upon the extent of destruction of the enemy and also on the preparation of the attacking troops for rapid negotiation of natural and artificial obstacles and obstructions in the terrain. Under conditions of the mass use of nuclear weapons and the increased mobility of troops, their advance at a rate of 100 kilometers and more in a calendar day is quite possible. However, in order to realize such rates of advance of the troops, it is necessary to inflict such destruction on the enemy that he would be deprived of the capability of offering serious resistance to the attacking troops or of creating radioactive contamination of the terrain in the zones of the offensive. Under other conditions, chiefly with a lesser degree of enemy destruction, the rates of advance of the front troops naturally cannot be as high.

The duration of offensive operations of a front at the highest indices of their scope may reach 8 to 10 calendar days. With lower indices of scope of the offensive operations of a front, their duration will be considerably greater.

Thus, under the influence of the mass use of nuclear weapons and the increased mobility of troops, not only have the indices of the scope of the offensive operations of a front changed, but also their nature. Now the troop advance, as a rule, will be carried out in wide zones, on separate and disconnected axes, by the method of simultaneous and successive destruction of the enemy. The advance of the troops will develop at high rates in order to penetrate swiftly and rapidly into the operational-strategic rear of the enemy. However, on account of the perfectly natural tendency of the enemy, by extensive use of nuclear weapons, to accomplish his tasks also by means of an advance, the most frequent type of combat operation of troops in modern offensive operations will be the meeting battle and meeting engagement.

The high degree of maneuver in a modern offensive operation almost completely precludes the penetration of the enemy's defenses in its past meaning, since his defenses will not have the continuous

[redacted]

1.3(a)(4)

1.3(a)(4)

[redacted]

[redacted]

1.3(a)(4)

fronts and the high density which they formerly had.

While,up to now, this article has discussed the overall influence of nuclear weapons on the principles of offensive operations of a front, we would now like to emphasize its special characteristics, the radioactive contamination of the terrain. It should always be taken into consideration that troop personnel operating on terrain contaminated by radioactive substances can be disabled as a result of radiation sickness.

It is known that this casualty factor is most insidious, since it does not have any apparent external symptoms and can be detected only with dosimetric instruments. The greatest radioactive contamination of the terrain endangers troop operations, and occurs with nuclear surface bursts. Radioactive contamination of the terrain in areas of nuclear air bursts and in the path of movement of a radioactive cloud is considerably less and is less dangerous to troop operations.

It also should be kept in mind that the fallout of radioactive dust, and consequently, the level of radiation on the contaminated terrain, will vary. As regards the duration of radioactive contamination, if at ground zero it is lethal for a considerable period of time, the levels of radiation in the path of the cloud gradually diminish and cease to be lethal.

It is obvious that as a rule nuclear surface bursts will be employed against troops and installations located in the operational depth under favorable operational and meteorological conditions. Wherever these conditions are favorable for the attacking troops of a front, they naturally preclude the possibility of enemy nuclear surface bursts and, conversely, wherever the front troops, because of operational and meteorological conditions, cannot employ nuclear surface bursts, they will be advantageous for the enemy. Hence, it can be assumed that during the course of an operation up to 25 percent of all nuclear warheads of both sides can be employed with surface bursts.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Let us suppose that in the zone of the immediate task of a front, equal to 120,000 square kilometers, both sides, for the fulfillment of their combat tasks, use up to 200 different nuclear warheads, or half the total supply allotted to the operation, of which 25 percent, or 50 nuclear warheads, involve surface bursts. If, for example, 25 nuclear warheads have a yield of 10 kilotons and each of the remaining 25 of 100 kilotons, then in the general area of radioactive-contaminated terrain, equal to approximately 60,000 square kilometers, almost 9,000 square kilometers of terrain will be contaminated with dangerous levels of radiation from 50 roentgens and higher. Furthermore, it should be taken into account that with the mass use of nuclear warheads overlapping of the zones of radioactive-contaminated terrain and the creation of dangerous levels of radiation will inevitably occur, where the single bursts would not have been dangerous.

Even from this estimate the great significance of the casualty factor which arises as a result of the radioactive contamination of the terrain, and its influence on the course of the operation, are evident. However, it should be taken into consideration that the data of this estimate are more likely too low than too high, since in reality in the zone of the immediate task of a front both sides can employ more nuclear warheads with surface bursts and with a more powerful charge. Furthermore, in the present estimate no account has been taken of the fact that the zones of radioactive contamination can be especially designed to follow water and other natural boundaries, and to cross the axis of the troop offensive with the task of delaying the enemy or stopping his offensive. It should be kept in mind that the zones of radioactive contamination are not distributed uniformly throughout the whole of the zone of the front offensive, but as a rule will be created on the axis of the main and other strikes and will reach the greatest extent and the most dangerous levels of radiation there. In short, radioactive contamination of terrain has become a most important factor of operational-strategic significance. Without constant prognosis of the radiation situation, continuous study of it and reconnaissance of the probable zones and strips of radioactive contamination, and also without the prudent adoption of measures for the immediate withdrawal of troops from these zones

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted] 1.3(a)(4)

and strips or for their rapid crossing, the success of offensive operations cannot be guaranteed. With this aim, a chart of the radiation situation must be kept constantly in all staffs, especially in the operational staffs. The commanders of troops and the commanding officers of large units and units are obliged to know the radiation situation at all times and to take account of it in their decisions, orders, and operations.

Neglect of these requirements in a combat situation, or insufficient attention to them, may lead to unnecessary mass troop loss and to a deceleration of the rates of their advance.

The withdrawal of troops from the zones of radioactive contamination prior to the beginning of the operation may take place along the shortest axes on the initiative of the commanding officers of large units immediately after the detection of contamination, but crossing through such zones and strips during the course of an offensive operation, as a rule, will be carried out only on the decision of the commander of the front troops or with his sanction in order not to upset the plan of the operation.

The methods of crossing through these zones are determined by the axes, the dimension, and levels of radiation. If these zones do not completely intersect the axis of the troop advance and are not too extensive, then the most advisable method of crossing through them may be a detour not requiring a great deal of time.

When the zones and strips of radioactive contamination intersect the axes of the troop advance, and bypassing them does not appear possible, crossing through such zones and strips must be carried out by forcing them along routes with the lowest levels of radiation. Under conditions where high levels of radiation exist on all probable routes across the zone of contamination, it is advisable that the forward movement of troops be postponed until some abatement of these levels, but with the impossiblity of doing this, they immediately f orce the zone with tanks. Crossing through zones of radioactive

[redacted] 1.3(a)(4)

[redacted] 1.3(a)(4)

[redacted]

1.3(a)(4)

contamination must be carried out at increased speeds, with increased distances between vehicles, subunits and units and with the best use of means of individual protection.

In isolated cases, depending on the situation, continuous zones of radioactive contamination can be crossed by small units of troops in helicopters.

Furthermore, one cannot but consider the necessity for complete medical processing of the personnel of units and large units, and also the decontamination of their armament, equipment, and transport immediately after the troop crossing of zones and strips of radioactive contamination. Even with the thorough preparation of troops, medical processing and decontamination will require considerable time, but, as is known, an offensive penetration, especially under modern conditions, cannot tolerate any interruption. Therefore, the problem of the continuity of the offensive under modern conditions acquires especially important significance. Its solution depends mainly on the ability of the troops to cross the zones and strips of radioactive contamination rapidly and without great losses. Furthermore, for a more complete solution of this problem, it is necessary to envisage the swift maneuver of reserves from the rear to bypass the zones and strips of radioactive contamination and subsequently to emerge on the axis of the main and other strikes, frequently in conjunction with the dropping of forward units on these axes.

The views stated in this article are an attempt to examine briefly the influence which is exerted by the mass use of nuclear weapons (having due regard for other qualitative changes of troops) on some of the principles of modern offensive operations of a front.

In a short article, naturally, not all the principles of offensive operations could be examined. Therefore, such important questions as the influence of nuclear weapons on the support of front troops and on coordination, control, etc., were not touched on in this article.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

It should also be taken into consideration that further development of nuclear weapons will without doubt reinforce the firing, striking, and maneuvering capabilities of troops, and consequently, will bring about appropriate changes in the principles of modern offensive operations of a front.

A correct understanding of the influence of nuclear weapons on the principles of modern offensive operations of a front is undoubtedly necessary for the successful practical work of generals and officers regarding the preparation and conduct of these operations.

In the development of military-scientific thought in this and other directions of the growth of the military art, and also in the realm of the structure of the armed forces, we must not only remember but also persistently carry out, the orders of the Minister of Defense of the USSR, Marshal of the Soviet Union R. Ya. Malinovskiy to the effect that "at the present time, when our Armed Forces are at a critical stage of development, further thorough working out of military doctrine, of the theory of the military art, and of other questions of a military nature has acquired special significance. We must clearly realize that without marked improvement in military-theoretical work, practical errors in the building up of the Armed Forces are possible."[1]

1.3(a)(4)

Some Factors Affecting the Planning of a Modern Offensive Operation

by

Colonel-General Ye. Ivanov

The concept that the planning of a modern operation should be based primarily on the capabilities of nuclear weapons and their most effective utilization, which now appears to be the decisive factor in achieving victory over the enemy, has become universally recognized. However, it would be useful to examine some particular factors affecting the planning of operations.

In this connection, the first point on which we must dwell is the clarification of the concept "the main strike and the number of strikes in an operation."

In the past, the direction of the main strike for a breakthrough of a solid positional defense, which was typical, was always selected in support of the most effective use of the infantry, artillery, and tanks which were concentrated for the delivery of a strike on the weak spot on a selected axis, as a rule, in narrow zones, for subsequent destruction of the basic enemy grouping. This axis had precise limits in an operation and required compulsory superiority over the enemy in forces and weapons. This, naturally, had its definite influence on the content of the planning of the operation.

Under modern conditions, atomic weapons without the aid of other weapons of combat can, in the shortest periods of time, destroy the basic enemy troop groupings and deprive them of their combat effectiveness and in this way ensure an advantageous correlation of forces for the delivery of strikes and the development of an offensive.

Hence, when working out a solution and planning an operation, primary attention must be given to the determination of the sequence of the utilization of nuclear/missile weapons, which would guarantee maximum effectiveness of the latter in the destruction and neutralization of enemy groupings in the entire depth of the tactical and operational formation.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

With such a solution to the problem, very often on the axes and through the areas where nuclear weapons will be used (4 to 5 words missing) groupings of ground troops or in general to circumvent these areas in avoidance of a sharp deceleration of the rates of advance as a result of the serious destruction of populated points, of road structures, and of radiation contamination of the terrain.

It appears that the concept "main strike" under modern conditions and on an operational scale is primarily a mass nuclear strike against the enemy's nuclear weapons and his basic troop groupings which is followed by strikes with tanks and infantry on several axes, and no longer against a solid positional defense, but against a defense having primarily a clustered nature (ochagovyy kharakter).

In resolving the problem of the quantity of strikes, the mechanical transfer of the experience of the past war to modern conditions must be decisively rejected in a front and an army because of the still extant conception of the inadvisability for a front to deliver more than two strikes and of the impossibility for an army to deliver a strike on more than one axis. Substantiation of this leads to assertions which are far from the truth, namely that with a large number of strikes a front, and even more, an army, will dissipate its forces and will not be able to perform the assigned mission.

If concentration and utilization of a large mass of fire and of considerable masses of troops were required to execute a breakthrough in the past, now it can be carried out much more simply. Now nuclear/missile weapons are capable of breaking through an enemy's defense over large areas not only along a front but in depth and to form in it such breaches and even vacuums as to lead not only to the weakening of the enemy but also to his complete loss of combat effectiveness on the axes selected for the offensive. Thus, conditions have been created in which the operations of ground troops are possible without amalgamating them into some sort of a dense striking force.

Consequently, if one speaks of strikes, keeping in mind the axes of ground troop operations, there can be several of them, both of an army and of a front. Their number will be determined by the capabilities of the nuclear/missile weapons, the advantages of utilizing them, and also by the conditions supporting convenience in the operations of large units of ground troops.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

The delivery of several strikes by a front and an army, united by a common concept and directed toward the achievement of the assigned goals of an operation, is advantageous not only from the point of view of the availability of possibilities for ensuring these strikes by nuclear/missile weapons but also because with this, favorable conditions for achieving surprise are created. Dispersion of troops in several areas and over a large expanse together with the execution of other measures for operational concealment hinders the enemy in the timely determination of the intentions of the attacker. This will permit concealment from the enemy of not only the actual employment of the troops in an operation but also of the nature of the utilization of nuclear/missile weapons.

The operations of front (army) troops on several isolated axes create more favorable conditions for the utilization of the most varied forms of operational maneuver, permit a comparatively easy change in the direction of operations, especially during the course of the operation's development, and a quick transfer of the efforts of the troops into the depth. Furthermore, such conditions considerably simplify the use of various arms of troops since excessive congestion and shifting of their combat and precombat formations are eliminated, they permit a more effective utilization of the terrain, assist in the better organization of the work of the rear services and in particular, permit a more rational utilization of the main railroad and vehicular highway networks, and also of bridges and rivercrossings in support of supply and evacuation.

It is perfectly obvious that troops dispersed along a front for operations on various axes cannot be equivalent in composition or equipment. The content and importance of their missions will also differ. But they will be united by a single concept and the efforts of the troops will be directed toward the achievement of the overall goal of the operation. Moreover, now it is not important how many groupings have been created in a front for an offensive, but rather how the troops are organized for the most effective exploitation, at high tempos, of the results of the use of nuclear/missile weapons. Therefore, dispersion of troops along a front does not at all mean that their efforts are dissipated as a result.

The spatial scope, tempos and the duration of an operation must also be examined in a different manner from that which is still the practice at the present time.

1.3(a)(4)

[redacted]

1.3(a)(4)

First of all, the establishment of rigid and constant sizes in relation to the width of offensive zones loses its significance, especially for operational formations. In reality, when planning an operation, a front (army) will be assigned zones, determined not on the basis of some constant size, but rather on the basis of such factors as the composition and condition of the troops, the availability of nuclear/missile weapons, the possibility of organizing not only simultaneous neutralization of the enemy by fire in the entire depth and by a strike against the enemy from the front, but also the effect on him of airborne troops and motorized rifle units and large units transported by air, and also (and this is very important!) by the necessity to support an extensive maneuver of troops in the course of an offensive both for the delivery of simultaneous and successive strikes against the enemy from the most advantageous axes as well as for protection from his nuclear weapons.

From this, it is obvious that the principle of planning an army offensive operation is a zone 50 to 70 km wide with a breakthrough of the enemy's defense on a front of 25 to 30 km is outmoded. If this principle is examined carefully, it will be found to hide nothing more than an indirect requirement for the necessity, even now, to concentrate a large number of men and equipment on a sufficiently limited area (even if for only a brief span of time), i.e., as previously, to accomplish the tasks of breaking through the enemy's defense by an avalanche of troops and not by the power of modern fire and maneuver.

It appears to us that at the present time an army can, right from the beginning of an offensive, conduct it successfully in its entire zone or even in a significantly wider one than indicated above, including an offensive against a prepared enemy defense.

It is all the more possible that the basic methods of its operations will be mutually coordinated, in space and time, maneuvering operations of its individual large units, which come into direct contact with each other only in cases when the efforts of several large units are required against some particular enemy grouping. Under these conditions, moreover, even the large units of an army may often have to operate as individual units in wide zones. Consequently, in planning an operation, the offensive zone of an army should be such as to permit conduct of maneuvering operations both at the beginning of the operation and during its development and to provide a capability to concentrate the strength of the strike by means of the reserves dispersed in depth. Apparently, a zone of 100 to 150 km, in the

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

absence of a solid front, will ensure such operations to the highest degree to the troops of an army, particularly under conditions of considerable radioactive contamination of the terrain, which will better assist the fulfilment of assigned missions, and will undoubtedly lower the possibility of their destruction by the enemy's nuclear/missile weapons.

The necessity for maximum exploitation of the capabilities of nuclear/missile weapons for the speediest shifting of the efforts of a front's (army's) troops into the depth of the enemy's defense aimed at his final destruction and the seizure of the enemy's means of using nuclear ammunition and his missile weapon bases, engenders a legitimate desire to sharply increase the rates of offensive, which is now proposed to be 80 to 100 km per 24-hour period.

In connection with such a presentation of the problem of offensive tempos, we think that 80 to 100 km can be only an average daily rate with the presence of completely favorable conditions of the development of the operation.

Daily troop movement of 80 to 100 km can take place only with the absence of any enemy activity and, obviously, this cannot be counted on for the course of the entire operation; this is confirmed by past combat experience and by the experience of all exercises.

High offensive tempos and inevitable losses will, naturally, demand a high degree of strain on the troops and consequently the timely relief of large units of the first echelon, who have borne considerable losses and have lost their combat effectiveness as a result of the enemy's nuclear strikes. This very factor must be carefully appraised in order to correctly plan the conduct of operations at high but realistic rates, determined in light of the concretely developing situation. From this it appears that in each specific case, depending on the goals of the operation and the capabilities of the nuclear/missile weapons at hand, the indicated rates can vacillate to one side or the other.

Further, to the extent that as a result of the use of nuclear/missile weapons by both sides considerable areas of the terrain will be transformed into solid radioactive fields and because of which the engagement will break up into individual centers of combat over a

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

wide expanse, it must be assumed that the planned movement of ground troops will not take place as was done during the years of the past war. For example, an operation can begin with the simultaneous use of nuclear/missile weapons and of ground troops over the entire depth of the enemy's operational formation and will conclude as soon as the surviving centers of resistance have been destroyed, and the enemy's potential for undertaking any serious countermeasures to regain its lost position or to reestablish equality in forces on a given axis has been paralyzed.

With this method of conducting an operation, the degree of fulfilment of the assigned missions must be provided for in the plan of operation not by the number of kilometers covered by ground troops but by the possibility of seizing as much of the enemy's depth as possible through active combat operations including airborne landings, in order to paralyze his freedom over significant expanses and to bring to naught his efforts to continue resistance. Under such conditions, the most important thing is to calculate correctly the time necessary for a particular front or army grouping to conclude the destruction of the enemy in individual areas of resistance.

Of considerable importance in planning an offensive operation is its depth, which also cannot be of constant magnitude and which depends on the goals of the operation, the scale of use of nuclear/missile weapons, and the distance from the enemy's key operational-strategic objectives, which the front (army) must seize. In the category of these objectives which have a decisive influence in the determination of the depth of the operation and consequently the depth and content of the front's (army's) missions, the enemy's political-administrative and economic centers, important supply junctions, and the disposition areas of the enemy's bases of nuclear/missile weapons should be included.

The factors which in the past influenced the planning of the rates, the depth, and the duration of operations, such, for example, as the need for a front (army) to use force against the enemy successively depending on the means of destruction on hand for this goal, the depth of its operational formation, the possibility of a lag in airfield basing of aviation, of artillery, and a number of other things, which, if they must be considered at the present time cannot be determining because the capabilities of nuclear/missile weapons are actually limitless and, therefore, conditions for significantly speedier destruction of enemy groupings and the seizure of his territories are created.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

At the present time, as is known, it is customary to plan offensive operations by missions, in which all intermediate missions composing the substance of the immediate and subsequent missions of a front are included.

Thus, in planning for the execution of a front's immediate mission, the subsequent execution of the following intermediate missions is usually envisaged: the breakthrough of the tactical depth of the enemy's defense and the destruction of his nearest reserves, the seizure of the army zone and of the intermediate zones, the encirclement and destruction of the enemy by the forces of the front or, in coordination with adjacent units, the forcing of water obstacles, etc.

This type of mission assignment is connected in principle with methodical operations of the troops with their relatively steady movement on a solid front, from one line to another.

Moreover, modern conditions, operations of the troops of a front will be completely different and will not resemble the operations of the period of the past war, since both an offensive and defensive will be conducted on different principles.

The shifting of troops to an offensive will be effected, as a rule, from areas removed from the line where both sides are in direct contact; broad maneuver must be incorporated in the methods of troop operation, based on a combination of swift movement in columns with operations in precombat and combat formations along separate axes with subsequent conduct of individual engagements and battles in individual areas on a large expanse. Moreover, on some axes groupings of troops will advance swiftly, on others they will conduct meeting battles and engagements, temporarily withdraw, circumvent vast zones of radioactive contamination, changing the direction of advance or wait for a time.

Deep mutual breaking in by troops will become a normal phenomenon. Loss of direct contact of advancing and defending troops will take place frequently. An airborne landing may at times be the only possible way for the speedy fulfilment of the goals of the operation because (2 to 4 words missing) mass nuclear/missile strikes, whole expanses may become inaccessible for operations from the front of troops for an extended period of time.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

Armies of a front will advance, exposing themselves to enemy nuclear strikes, encountering the fierce opposition of his individual mobile groupings in separate areas, with which it will be necessary to wage heavy battles and engagements, and then to swiftly advance at rates close to those of marches, in order to seize the more deeply deployed objectives or to destroy the enemy groupings which are covering them.

As a result of the nature of combat operations by troops of a front, the rates of advance of the armies operating in the first echelon, and of the divisions which are part of the complement of the armies will be most uneven. Therefore, under conditions when the enemy's defense has lost its clearly expressed positional nature, when the mobility of the troops has significantly increased, and combat operations in the absence of solid fronts have become exceptionally maneuverable, by which both sides, in the course of executing combat operations will strive to deliver powerful deep strikes in order to break through into the depth of the territory along separate axes to seize the most important areas and objectives. The seizure of certain lines will not be a necessary condition for the complete defeat of the troops of the enemy whose groupings will also be maneuvering on the battlefield.

The assignment of missions by lines binds the maneuver capabilities not only of tank but also of combined-arms armies and paralyzes the commanders' initiative in their choice of the method of operations and the direction of a strike when deciding on missions for the destruction of the enemy.

One should also keep in mind that the basic fire strike force are nuclear/missile weapons on whose destrudive power the success of the operation depends in the final analysis, but these weapons, as is known, are not permanently located in some limited area. They are dispersed in the depth and along the front, practically throughout the entire zone of the defender.

With movement of our troops, the bases of the enemy's nuclear/missile weapons will be changing all the time, therefore, the arrival of troops of the front (army) at some given line still does not ensure the mission of routing the enemy.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

On the basis of the above, we come to the conclusion that the content and character of their assignment to the troops must be changed and brought into accord with the new methods of combat operations of troops.

The missions of a front (army) must be assigned so that their content does not bind the commander to the seizure and holding of certain lines on a solid front, but so as to have their fulfilment lead to the achievement of a perfectly definite operational or operational-strategic result.

In this, the main attention of the commander and staff should be aimed, above all, at the destruction (neutralization) of the enemy's nuclear/missile weapons, on the destruction of his basic groupings and the seizure of individual areas having important significance for the further development of the operation.

For example, the most immediate mission of a front in the initial period of a war can be the destruction (neutralization) of the enemy's nuclear/missile weapons along the entire depth of his operational formation, the route of the first operational echelon of the opposing grouping by gaining the main routes of approach of the major enemy reserves, and prevention of their inflow and unification for a strike against the troops of the front.

A subsequent mission of a front can consist of the destruction of the enemy's nuclear/missile weapons that have remained intact or have newly appeared, the destruction of deep reserves, the seizure of the primary areas of his missile bases, political-administrative or economic centers, and also the disruption of mobilization measures in a particular area of the country.

However, in these questions also, we must decisively reject our accepted practice of strict centralization and detailing of missions. The experience of war shows that the degree of detailing in assigning missions to troops depended, in every case, on the scale and the designated purpose of formation and large units, on the specific conditions of the situation and the nature of the combat activity of the troops. In this, great independence in operations was permitted at the operational level and to a lesser extent at the tactical. During the war, there was also a very clear expression of

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

the tendency toward strict centralization of control in the preparation for an operation and combat and a relatively smaller degree of centralization in the process of their conduct. At all levels, centralization of control by the senior commanders also took place with regard to the utilization of fire and strike means.

However, in the course of the past war it had already become evident that strict centralization of control is applicable in those forms of combat operations where the troops lack a capability for an extensive maneuver, for example, during a breakthrough of a prepared positional defense and also in instances when the qualities of the troops are not adequate for maneuvering. But as soon as conditions were created for an extensive maneuver of forces and weapons, the necessity immediately arose to switch from strict centralization to granting subordinates more initiative and independence in accordance with the specific situation within the framework of the general operational concept.

Under the conditions of highly dynamic combat operations and abrupt changes in the situation, it would hardly be correct to centralize the control of troops right up to the point of indicating to large units and units the methods for fulfiling their combat missions, as sometimes happened during the past war. The increased combat capabilities of troops, the nature of a modern battle and operation now urgently require granting subordinates greater independence and the opportunity to manifest initiative in operations in all instances.

Of course, the degree of centralization of control, even under new conditions will depend on the specific situation which has taken shape, the nature of the combat operations, and the preparedness of command cadres and staffs at all levels of the military organism.

Under certain situational conditions, the senior commander, in addition to assigning missions to subordinate troops and allocating to them the means of reinforcement, can define the method by which the assigned missions are to be fulfilled, under others, he can apportion to subordinate troops the necessary means for reinforcement and indicate combat missions without predetermination of the methods of fulfilling them and the sequence of the use of forces and weapons, granting this right to the subordinate commanders.

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

[redacted]

1.3(a)(4)

However, the general trend in the development, characteristic of troop control under modern conditions, must lead to subordinate commanders and staffs using greater freedom and independence than was the case, for example, in World War II.

The circumstance, that a tendency has been clearly noted to change the combat composition of the operational formations of the front and armies, in the direction of a quantitative reduction also has very great significance for the planning of an operation.
